These few data are in fairly good agreement with those given by Sawkins *et al.*<sup>1</sup>, and generally support the low-temperature origin of the vein assemblages. Hexagonal pyrrhotite with a (102) spacing of 2-088 Å was not, however, detected by me. There are apparently no reliable records of homogeneous natural pyrrhotites having compositions between those of troilite and intermediate pyrrhotite ( $\text{Fe}_{0.912}\text{S}$ ), perhaps reflecting the presence of a solvus between these compositions at temperatures below c. 200° C (von Gehlen; personal communication). Cooling of iron-rich pyrrhotites from moderate temperatures (> 250° C) probably invariably results in the mutual exsolution of troilite and intermediate pyrrhotite, but primary crystallization at low temperatures might permit the formation of, presumably, metastable pyrrhotites within the proposed two-phase region.

WE welcome the preceding communication by Dr. A. H. Clark, which does much to clarify the problem of low-temperature pyrrhotites. We wish to point out that our only intention was to question the use of experimentally inverted monoclinic pyrrhotite as a geological thermometer (Buseck<sup>1</sup>, Kullerud *et al.*<sup>2</sup>) and to show that in some natural occurrences the use of inverted monoclinic pyrrhotite produced results at variance with independent temperature data obtained from fluid inclusions.

## GEOCHEMISTRY

### Fixation of Nitrogen by Aurora and its Contribution to the Nitrogen Balance of the Earth

CONSIDERABLE amounts of energy are dissipated in the upper atmosphere of the Earth by such geophysical phenomena as aurora, air glow and particulate bombardment. It is generally believed<sup>1</sup> that the dissipation of this energy leads to the formation of chemical species among which are oxides of nitrogen or their corresponding charge species. If these chemical species could reach the surface of the Earth they would contribute nitrate and nitrite to the biosphere. One of the aims of the Eighth Victoria University Antarctic Expedition was to estimate the magnitude of this effect by the chemical analysis of snow at the South Pole.

The South Pole was chosen because (a) thunderstorms, the usually accepted source of  $\text{NO}_2'$  and  $\text{NO}_3'$  in the atmosphere, are unknown; (b) if snow is collected from depths corresponding to times before human activities at the Pole, the chances of biological contamination are diminishingly small. The South Pole, being situated at 9,300 ft. on an ice plateau, is so remote that all normal sources of possible contamination can be eliminated; (c) the South Pole is surrounded by the auroral zone.

Freshly fallen snow (November 3, 1963) and snow from the year 1962–63 was collected one mile from South Pole Station. Samples of snow from 3 ft. inside the wall of the snow mine 44 ft. below the surface (approximately 100 years old) were analysed at the Base for  $\text{NO}_3' + \text{NO}_2'$  using the phenoldisulphonic acid method as described in ref. 2, except that a 500-ml. sample was used. All samples measured contained 0-005 p.p.m. N as  $\text{NO}_3' + \text{NO}_2'$ .

The nitrate plus nitrite content of South Polar snow was almost equal to that of the chloride content (0-027 p.p.m.). This is in marked contrast to analysis of snow from other areas less remote from the oceans<sup>3</sup>. Since the accumulation of snow at the South Pole is 8 g/cm<sup>2</sup>/yr., it follows that the yearly infall of nitrogen as  $\text{NO}_3'$  and  $\text{NO}_2'$  is  $5 \times 10^{-8}$  g/cm<sup>2</sup>/yr., which is 0-005 kg/hectare or 0-0045 lb./acre.

Another possible source of this material is extraterrestrial. Whipple<sup>4</sup> has reviewed the evidence for the infall of meteoric material and gives an accretion of 1,000 tons of meteoric material per day for the whole Earth, which is 0-007 kg/hectare. This is inadequate to provide the amounts of fixed nitrogen observed.

The conclusion from this work is that the annual infall of nitrogen as nitrate and nitrite at the South Pole due to geophysical phenomena in the upper atmosphere is less than, or equal to, 0-005 kg/hectare (0-0045 lb./acre).

## METALLURGY

### Direct Evidence for Three Transformation Mechanisms for the $\beta \rightarrow \alpha$ Phase Change in Uranium - Chromium Alloys

PURE uranium exists in three allotropic forms:  $\alpha$ , which is orthorhombic and stable up to 667° C;  $\beta$ , which is tetragonal and stable between 667° and 775° C; and  $\gamma$ , which is body-centred cubic and is stable between 775° C and the melting point 1,132° C. In the pure metal the phase changes occur with great speed, and investigation of the mechanisms of the changes is extremely difficult. The addition of small concentrations ( $\sim 0.5$  atomic per cent) of certain solutes, of which chromium is one, retards the  $\beta \rightarrow \alpha$  change so effectively that  $\beta$  can be retained at moderate cooling rates to sub-critical temperatures and then allowed to proceed isothermally. White<sup>1</sup> and others<sup>2,3</sup>, using either dilatometric or metallographic techniques, showed that the time-temperature-transformation (TTT) diagram associated with isothermal  $\beta \rightarrow \alpha$  transformation in various dilute uranium alloys consisted of two separate C-curves. Metallographic and crystallographic investigations<sup>4-7</sup> have shown conclusively that the low-temperature C-curve (hereafter referred to as  $C_2$ ), which in U-0.5 per cent Cr alloy extends from room temperature to about 400° C, is associated with a martensitic mechanism. It was supposed that the upper C-curve, covering the range 400°-620° C in this alloy, was associated with transformation involving thermally activated atomic movement. However, metallographic observation showed that the micro-structure of the  $\alpha$  formed at temperatures between about 525° C and 620° C was quite different from that formed between 525° C and 400° C, suggesting that two formation mechanisms were possible, one in each temperature range. In order to explore this possibility further Dixon and Burke<sup>8</sup> redetermined the TTT diagram for a U-0.5 atomic per cent Cr alloy using an electrical resistivity method which was regarded as a more sensitive technique than those used in previous investigations. Evidence was found to suggest that the upper C-curve was composed of two overlapping C-curves, intersecting at about 520° C as required by the two-mechanism hypothesis.

Unfortunately, Dixon and Burke's evidence for the third C-curve was only indirect. The temperature coefficients of resistivity of the  $\alpha$ - and  $\beta$ -phases are quite different with the result that the magnitude of the change in resistance accompanying the phase change, which determines the sensitivity of the method, varies with the temperature of transformation, being about +4 per cent at 620° C, 2 per cent at 400° C, and zero at approximately 520° C. Thus the sensitivity was least in the critical temperature range. Since it is clearly desirable to get direct confirmatory evidence of the proposed third C-curve a detailed examination has been made of the phase change in other

Fig. 1. The time-temperature-transformation diagram for the  $\beta \rightarrow \alpha$  phase change in U-0.85 per cent Cr alloy

uranium-chromium alloys. In the case of an alloy containing 0.85 atomic per cent Cr, it was found that the temperature of zero resistance change was raised relative to that in U-0.5 per cent Cr, enabling the division into separate C-curves to be firmly established for the first time.

The technique used was basically that described by Dixon and Burke<sup>8</sup>, although several modifications were made to improve the accuracy of the resistance measurements and to improve the quench speed. Wire specimens, 0.025 in. diam., were mounted in an evacuated silica tube and surrounded by a furnace controlled at a selected temperature in the  $\alpha$  range. The temperature of the specimen was then raised to 710° C by passing an electric current through it. After holding for 5 min, the specimen was quenched back to the furnace temperature by switching off the current and injecting argon over the specimen. With this technique quenching times of less than 5 sec were achieved. Changes in resistivity accompanying the  $\beta \rightarrow \alpha$  phase change were measured continuously using the potential drop method, the potential across the specimen being recorded on a potentiometric strip chart recorder.

The complete TTT diagram derived from the resistivity measurements is shown in Fig. 1. No results could be obtained between 560° and 585° C because the magnitude of the resistance change in this range was too small to give reasonable sensitivity. This is some 50° higher than the corresponding range in U-0.5 atomic per cent Cr. The upper C-curve contains a well-defined cusp in the range 470°-500° C. This cusp is formed by the overlapping of two C-curves as suggested by Dixon and Burke. It is convenient to refer to the higher temperature one as  $C_1$  and the lower one as  $C_2$ . Fig. 1 is considered to fully establish the existence of three C-curves in the TTT diagram for the  $\beta \rightarrow \alpha$  phase change in U-Cr alloys.

The microstructures of the transformation products were similar to those described by Dixon and Burke<sup>8</sup> and

Beaudier, Cabane and Mouturat<sup>3</sup>. In  $C_1$  the  $\alpha$  was equiaxed and the grain size decreased with temperature of formation; in  $C_2$  the  $\alpha$  had a fine acicular structure.

It follows from this work that the  $\beta$ -phase can transform to  $\alpha$  by three mechanisms. In  $C_1$  the insoluble chromium is precipitated, showing that long-range diffusion is involved. Electron microscope evidence indicates that this is a eutectoid type process<sup>4</sup>.  $C_2$  is clearly martensitic<sup>4-7</sup>. However, the evidence relating to  $C_2$  is scant. Dixon and Burke suggested that this curve corresponded to a reaction in which supersaturated  $\alpha$  is formed by shear of the  $\beta$  and the insoluble chromium is simultaneously rejected from the  $\alpha$  lattice in the form of a fine precipitate. However, it can be seen by comparison of Fig. 1 with the TTT diagram of Dixon and Burke that increasing the chromium content from 0.5 to 0.85 per cent depresses  $C_2$  much more than  $C_1$  and produces a marked separation between the  $C_2$  and  $C_3$ . It is therefore arguable that the closer proximity of the two upper  $C$ -curves indicates that the mechanism in  $C_2$  is more akin to the known diffusional reaction in  $C_1$  than to the martensitic reaction in  $C_3$ . This would suggest that the phase change in  $C_2$  involves diffusion as the predominant process.

### Precipitation of Vanadium Carbide on Stacking Faults

THE precipitation of niobium carbide and titanium carbide in association with stacking faults in austenitic steels has been widely reported in the literature<sup>1-4</sup>. During the course of an examination of precipitation in high-alloy austenitic steels we have observed the precipitation of the vanadium carbide,  $V_4C_3$ , also in association with stacking faults.

The austenitic steel (25 per cent Ni, 20 per cent Cr, 5 per cent V, 2 per cent Si, and 0.15 per cent C) was solution treated at 1,200° C, water quenched and aged in the range 650° C–850° C. During the early stages of ageing,  $V_4C_3$  precipitated in association with stacking faults (Figs. 1 and 2). The precipitation phenomenon could be examined by both thin foil (Fig. 1) and carbon extraction replica (Fig. 2) techniques. The precipitation of  $V_4C_3$  in association with stacking faults brought about a substantial increase ( $\sim 50$  Vicker's pyramid number) in the hardness of the alloy. On further tempering the  $V_4C_3$  precipitates were replaced by  $\sigma$  phase, with a further increase in hardness of the alloy.

Details of the investigation will be given in a future publication. We would, however, like to point out some differences between our investigation and that of earlier work on the precipitation of NbC and TiC.

(1) In niobium- and titanium-containing alloys a solution temperature of 1,300°–1,350° C was necessary to induce this type of precipitation. In our work a solution temperature of 1,200° C was quite sufficient.

Fig. 1. Austenitic steel aged 17 h at 800° C (thin foil;  $\times 20,000$ )

Fig. 2. Austenitic steel aged 50 h at 750° C (carbon extraction replica;  $\times 50,000$ )

(2) The range of temperature (650°–850° C) over which the carbide precipitated in association with stacking faults was much wider than that for niobium- and titanium-containing alloys.

(3) From the earliest stages of ageing the  $V_4C_3$  particles were much coarser ( $\sim 80$ – $120$  Å) than the niobium carbide and titanium carbide particles ( $\sim 50$  Å) reported in previous work. This is in agreement with the proposed mechanism of stacking fault precipitation<sup>4</sup>.

(4) At no stage (including the shortest periods at 650° C) were stacking fault 'fringes' observed in thin foils.

## CHEMISTRY

## Sucrose Crystallization

PREVIOUS reports<sup>1,2</sup> described how static films of aqueous sucrose solution may be evaporated under controlled vapour pressure in humidators<sup>3</sup>, facilitating examination of nucleation and crystal growth throughout the whole range of supersaturation (SS). In these circumstances, when nucleation occurred at the higher concentrations, that is, more than 3.0 SS (ref. 2), spherulitic multicrystals were found to be the normal form. In many cases they closely resembled polymer crystal forms.

Nucleation may be much more speedily initiated by adequate movement within the film, either of some pre-existing sucrose crystal, or of some neutral body. In the latter case more violent movement is necessary<sup>4</sup>. In either case monocrystal nuclei result throughout the whole range of supersaturation, even in the near-glassy regions. By controlling the vigour of the movement the nuclei may be either well dispersed, or so crowded as to overgrow one another, and individual crystals 'assert themselves', developing with characteristic contour protruding from the formless mass. At sufficient dispersion an investigation of the component monocrystals is possible.

H. E. Buckley<sup>5</sup> and others have recorded a great deal of evidence of crystal habit modification by adsorption of certain impurities on one or more faces of a growing crystal. Experiments with sucrose reveal that extreme variations may result from the same solution of highly refined sucrose in distilled water by initiating nucleation at different concentrations. The evidence suggests that this is the logical result of variation in mechanism only, this being the more tenable hypothesis now that some variations in growth mechanisms are already known.

The monocrystals which result from movements in solutions at high SS appear to be remarkably uniform in size, rate of growth, and shape, appearing 'square' in contour. Every fresh movement results in a fresh genesis of similarly uniform monocrystals. Thus two or more 'generations' of crystals differing in size may be produced

Fig. 1. 'Late developer' acicular sucrose. Axis ratios observed exceeding 100:1.

Fig. 2. 'Late developer' sucrose, both acicular and square type

Fig. 3. Example of acicular crystals after extensive growth

Fig. 4. One 'generation' of extreme size variation nucleated at 1.1 SS

Fig. 5. Two 'generations' of uniform type

between two glasses under the microscope (Fig. 1). Below 2.0 SS this regularity becomes increasingly less evident.

At SS in the region of 1.6-1.3 the nuclei produced by crystal movement show considerable difference in form and uniformity of growth. In place of the 'square' contour the more familiar, somewhat rectangular, contour normally develops. (The usual sucrose crystal habit is  $100 \geq 110 \geq 001 > 1\bar{1}0 > 011$ ; H. E. Buckley, private communication.) More strikingly, acicular or needle-shaped forms appear—'late developers' (Figs. 2-4)—in the sequence of crystals growing to a size visible under the microscope. These needles are almost invariably the last to appear, occasionally accompanied by small groups of the square contour type. They sometimes resemble whiskers both in dimensions and mode of growth, and may indicate the existence of different nucleation mechanisms. By using a tall column<sup>4</sup>, with preferential subsidence of the more rapidly-growing crystals, the acicular form may be obtained almost exclusively.

Fig. 6. Two types of spherulite, one of which shows a visible sleeve of exhaustion

At SS in the region of 1.2–1.05 the nuclei initiated by crystal movement show really striking differences in rate of development, and hence in size<sup>2</sup> (Fig. 5). The investigations now reported were designed to provide further evidence on this subject. It would appear probable that a differential solubility effect becomes insignificant at supersaturations above 2.0, also that genesis of nuclei then operates almost exclusively by one mechanism, and that growth mechanism is similarly uniform. In the region of 1.2–1.05 SS, not only do crystals show great variation in rate of development in the same medium, but also time lapse cinemicrography shows fairly numerous cases of a sudden burst of growth in single crystals, sometimes mainly in one direction. This supports the suggestion that varied growth mechanisms may operate.

Another predictable effect of differential solubility has been successfully recorded by time lapse cinemicrography. Every crystal growing in a static supersaturated solution soon creates a zone or sleeve of lower supersaturation as crystallization proceeds<sup>4</sup>. In the case of a crystal growing in a solution of about 1.1 SS, a sufficiently small crystal entering this zone may be dissolved. This would not happen in a solution of high supersaturation since even the sleeve would still be well above the critical concentration. In fact, if the supersaturation of the medium were sufficiently high, the small crystal might be expected to grow more rapidly, since at sufficiently high supersaturation the rate of crystal growth decreases with increasing concentration. Actual instances of these phenomena have been filmed.

The sleeve of exhaustion may even be seen, under appropriate conditions, by the unaided eye<sup>6</sup>, but far more effectively by means of special optical techniques. Occasionally ordinary photomicrography is able to record it, as in the example here reproduced (Fig. 6). There are many types of spherulites and in the illustration two strongly contrasted types are seen growing in a film of highly supersaturated solution. The pointed type grows much more slowly, and the impurities (mainly water) are able effectively to disperse, but with the flat-fronted type a sleeve of exhaustion is clearly visible moving ahead of the crystal front. I regard the former as a true spherulite, the latter as a pseudo-spherulite which arose from the ultimate development of an original group of adjacent monocrystal nuclei. Growth on the surface of the true spherulite would be slower owing to the relative perfection of the lateral lattice.

Finally, in earlier reports details were given of methods whereby thin films of sucrose solution could be evaporated under completely undisturbed conditions, without nucleation, even to the glassy state. Random nucleation appeared to peak at about 2.5 SS, and it did not appear likely that grosser depths of solution could be so evaporated without the incidence of nucleation. It has since

been found that under conditions in which aerial contamination by potential nuclei is eliminated much thicker films can be obtained. Films 1–2 mm thick are relatively easily obtained, and several of 10–15 mm have been successfully carried to a near glassy state. This is an effective reminder that air-borne potential crystal nuclei may be of the order of  $10^{-3}$  of the diameter of air-borne organisms, and hence even more difficult to exclude completely.

### Identification of Carbonic Anhydrase in an Atmospheric Aerosol

BASED on the fact that the measured values of carbon dioxide of atmospheric air samples never could be determined as specific (using Pettenkofer's titration method  $\text{CO}_2$  values of 0.025–0.037 per cent/vol. were measured) a series of tests have been performed over a period of years to explain these irregularities. While some years ago the influence of light as opposed to darkness and the influence of temperature on the  $\text{CO}_2$  values could be proved<sup>1–3</sup>, the existence of a substance which acts as a catalyst and which seems to play an essential part in the deviations of the measured  $\text{CO}_2$  values was determined by these last tests.

As to the effects of daylight, darkness and temperature, the following facts are obvious: (1) Defined volumes of atmospheric air samples, which previously were stored in complete darkness for 3+ h and which also were titrated in darkness, in 90 per cent of all tests showed higher  $\text{CO}_2$  values ('dark values') than the corresponding  $\text{CO}_2$  values ('daylight values') achieved with air samples which had been exposed to daylight only. The remaining 10 per cent were equal to the  $\text{CO}_2$  values compared but the 'dark values' were never less than the 'daylight values'. The air samples stored in complete darkness nevertheless showed reversible character, that is to say, after a further irradiation in daylight those  $\text{CO}_2$  values were almost equal to the daylight values measured at the same time; (2) Atmospheric air samples, which were heated at different temperatures, showed no effects if the temperature was kept below 50° C. As soon, however, as the temperature exceeded the critical value of 50° C a rise in the  $\text{CO}_2$  values was observed in strict analogy with the  $\text{CO}_2$  values measured in air samples which had been placed in absolute darkness for 3+ h. The reversibility, however, was lost and the  $\text{CO}_2$  values represented an unchangeable value which could neither be raised nor lowered through the influence of light, darkness or temperature.

While it seemed obvious that the deviations may be caused by a photochemical effect in considering the results of the influence of light and darkness on the  $\text{CO}_2$  values, the tests with different temperatures suggested that the atmospheric aerosol contains a substance which becomes ineffective at temperatures higher than 50° C.

The latter suggestion was supported essentially by the results obtained when samples of air were sucked through asbestos filters (certain types of Schleicher and Schüll filters were used in these tests). In fact the air behind the filters proved to be absolutely inert and neither daylight, darkness nor temperature had further influence. Therefore the  $\text{CO}_2$  values of the samples were equal to the dark values or to the  $\text{CO}_2$  values obtained after having heated the air samples higher than 50° C.

Interpreting the fact that the air samples became insensitive to light and darkness after having been filtered, the postulation of a pure photochemical process has to be abandoned. It is suggested rather that any photochemical effect is only effective in the presence of a substance acting as a catalyst and will disappear as soon as this substance is removed from the atmospheric air samples by filtering off. Furthermore, the effect of temperature defined at 50° C gave a valuable hint for the identification of the substance itself and of its efficiency and stability as well. Considering the fact that among the innumerable organic compounds and complexes 50° C is a limiting temperature especially for the efficiency of enzymes, it was obvious, on consideration, that such an enzyme might exist in the atmospheric aerosol. Carbonic anhydrase is known as an enzyme, which can displace the equilibrium between  $\text{H}_2\text{CO}_3$  and  $\text{CO}_2$  according to the equation:

and the possibility that this enzyme might be existent in the atmospheric aerosol led to a further series of tests.

For these tests some cubic metres atmospheric air were pumped over glass frits into glass vessels, which were filled with  $\text{CH}_3\text{COOH}$  and  $\text{CHCl}_3$  and the extracts of these solvents were tested for amino-acids and for zinc (the central atom of carbonic anhydrase) with paper chromatography, after the solvents had been hydrolysed with hydrochloric acid. As blank test carbonic anhydrase (Light and Co., Great Britain) was used. Taking the nearly 100 chromatograms performed during these tests as a basis, the conformity between the test substance and the substance we removed from the atmospheric air was proved beyond doubt. At the same time another series of tests was performed whereby carbonic anhydrase was added to samples of air which first were made inert by filtering. The results were surprising, for samples of air which showed no deviations in their  $\text{CO}_2$  values except the high  $\text{CO}_2$  content, now after the enzyme had been added became sensitive to light, darkness and also temperature. Thus, the deviations of the measured  $\text{CO}_2$  values of atmospheric air samples appear to be solved since through the enzyme as catalyst and probably simultaneous influence of light the equilibrium will be displaced more to the left side of the equation, that is to say, strongly in  $\text{H}$  and  $\text{HCO}_3$  dissociating  $\text{H}_2\text{CO}_3$ . Consequently (the determination of the  $\text{CO}_2$  content according to Pettenkofer proceeds in  $\text{Ba}(\text{OH})_2$ ) the  $\text{CO}_2$  values appear to be less since two  $\text{HCO}_3$ -groups instead of one  $\text{CO}_3$ -group are bound to one barium ion. If the substance is missing very little of the  $\text{H}_2\text{CO}_3$  capable of dissociation remains and the atmospheric carbon dioxide in fact will be measured as pure  $\text{BaCO}_3$  in case the minimum dissociation of  $\text{CO}_2$  is neglected.

Concerning the concentration of the enzyme, certain tests induce us to believe that the concentration eventually depends on weather conditions.

## BIOCHEMISTRY

### Graphical Analysis of Enzyme Kinetic Data

THE velocity of an enzyme reaction,  $v$ , is usually related to the substrate concentration,  $s$ , by the Michaelis equation:

$$v = \frac{V}{\frac{Km}{s} + 1}$$

where  $V$  and  $Km$  are the maximum velocity and the Michaelis constant, respectively. To obtain values for these constants from experimental results, it is usual to use one of several algebraic transformations of the Michaelis equation, to obtain a linear plot. The one probably most widely used is that commonly attributed to Lineweaver and Burk<sup>1</sup>, namely:

$$\frac{1}{v} = \frac{Km}{V} \cdot \frac{1}{s} + \frac{1}{V}$$

where, by plotting  $1/v$  against  $1/s$ , a straight line is obtained intercepting the  $1/v$  axis at  $1/V$  and of slope  $Km/V$ . (Dixon<sup>2</sup> has also pointed out that  $Km$  may be obtained from the intercept on the  $1/s$  axis, which is  $-1/Km$ .)

A second transformation is that which has been attributed<sup>3</sup> to Eadie<sup>4</sup>; but it appears that both plots were devised by Woolf<sup>5</sup>. Here:

$$v = V - Km \frac{v}{s}$$

then by plotting  $v$  against  $v/s$  a straight line intercepting the  $v$  axis at  $V$  and of slope  $-Km$  is obtained.

Dixon and Webb have recently<sup>6</sup> reiterated their preference<sup>8</sup> for the Lineweaver and Burk plot. They have expressed the opinion that both plots are satisfactory with respect to the accuracy of the constants determined, but they object to the Eadie plot because: (a) it is difficult to identify the points with respect to their substrate concentrations; (b) more calculation is involved to obtain  $v/s$  for plotting.

Hofstee<sup>7</sup> has pointed out that in the Eadie plot all points for a particular substrate concentration are limited to a straight line, of slope  $s$ , which passes through the origin. It is very simple to construct such lines for each substrate concentration merely by choosing a convenient arbitrary value of  $v$ , which is a simple multiple of the value of  $s$ . The value of  $v/s$  can then be calculated (mentally) and plotted against  $v$ . When one such point has been marked for each of the required substrate concentrations, a series of lines are drawn from the origin through each of these points; and each line can be marked with the appropriate substrate concentration. Obviously the values of  $v$  should be chosen such that the points lie as close to the perimeter of the graph as possible. To plot the values of  $v$  against  $v/s$  it is then only necessary to mark the values of  $v$  on the appropriate substrate concentration lines. This method is illustrated for theoretical values of  $V=100$  and  $Km=0.0004$  M for substrate concentrations from 0.00005 M up to 0.0032 M, increasing by a factor of 2 for each successive member of the series (Fig. 1). This is the ideal situation<sup>7</sup>, where the concentrations increase geometrically, and the value of the middle concentration is the same as that of  $Km$  (ref. 8).

This application of the Eadie plot meets both the objections of Dixon and Webb. These authors have also

Fig. 1. Eadie plot for theoretical data,  $V=100$ ,  $Km=0.0004$  M.

### Specific Assays of some Phosphatases in Subcellular Fractions of Small Intestinal Mucosa

IN the mucosa of the small intestine, alkaline phosphatase (orthophosphoric monoester phosphohydrolase; EC 3.1.3.1) is known to be mainly localized in the brush border region<sup>1,2</sup> while glucose-6-phosphatase (D-glucose-6-phosphate phosphohydrolase; EC 3.1.3.9) is a predominantly microsomal enzyme<sup>3</sup>. Thus these two enzymes may be used as markers for the assessment of the purity of subcellular fractions obtained in fractionation studies. However, as pointed out by Ginsburg and Hers<sup>4</sup> and Triantaphyllopoulos and Tuba<sup>5</sup>, the assay of glucose-6-phosphatase is complicated by the fact that glucose-6-phosphate may be hydrolysed by more than one enzyme. Similarly, acid phosphatase (orthophosphoric monoester phosphohydrolase; EC 3.1.3.2) and alkaline phosphatase of the intestinal mucosa have a rather broad pH optimum. These two enzymes are therefore difficult to assay accurately by merely choosing buffers of different pH values. These difficulties can be overcome by the use of specific inhibitors. In the following, procedures are described for the assay of these three phosphatases which will give a more accurate determination of their respective activities than was possible with the assay systems so far known.

Clark and Porteous<sup>6</sup> reported on the metal requirement of the alkaline phosphatase from small intestinal mucosa. An inhibition study with ethylenediamine tetraacetic acid (EDTA) showed that the alkaline phosphatase of cat small intestinal mucosa was almost completely inhibited in the presence of 4 mM EDTA (see Fig. 1). The particulate preparation used in this experiment was prepared in the absence of EDTA. The addition of 1–8 mM Mg<sup>++</sup> ions to the assay system did not change the reaction rate. When adding increasing amounts of Zn<sup>++</sup> ions to the assay system a correspondingly increasing inhibition was observed. A 50 per cent inhibition was obtained at 0.15 mM zinc sulphate. Fig. 1 B shows the inhibition of acid phosphatase by potassium fluoride. There was an almost complete inhibition at 1 mM potassium fluoride. In the assay of acid phosphatase, the potassium fluoride-induced inhibition was not reversed by 4 mM EDTA. Likewise, the EDTA-induced inhibition of alkaline phosphatase was not influenced by 1–2 mM potassium fluoride. However, the addition of EDTA increased the reaction rate of the acid phosphatase in the absence of potassium fluoride (see Fig. 1 B). The stimulation brought about by 3–5 mM EDTA varied between 10 and 15 per cent.

In conclusion, acid phosphatase may be assayed by determining the potassium fluoride-sensitive hydrolysis of  $\beta$ -glycerophosphate at pH 5.4 and alkaline phosphatase by determining the EDTA-sensitive hydrolysis of  $\beta$ -glycerophosphate at pH 9.5. Under the assay conditions described for both enzymes in Fig. 1, the reaction proceeded linearly with time up to 20 min of incubation at 37°. Also, the reaction proceeded linearly with protein concentration when up to 2.5  $\mu$ moles of inorganic phosphate were liberated. The control experiments should contain the same additions as the test, except that 2 mM potassium fluoride or 4 mM EDTA is added. Subtraction of the amount of inorganic phosphate liberated in the presence of the inhibitors from that obtained in the tests will give the potassium fluoride or EDTA-sensitive hydrolysis of  $\beta$ -glycerophosphate. Thus this method does not require the usual enzyme or substrate controls. Because of the stimulation caused by EDTA, acid phosphatase should be assayed by adding 4 mM EDTA to both test and control experiment. It is essential that in the assay of the acid as well as the alkaline phosphatase the reaction is started by adding the substrate, since there is a time lag before the action of the inhibitors becomes fully effective.

Fig. 2. Lineweaver and Burk plot for same data as Fig. 1

discounted<sup>8</sup> the advantage claimed for the Eadie method<sup>3,7</sup> of a more even spread of points, where the substrate concentrations increase arithmetically.

They argue that a geometrical increase in substrate concentration is to be preferred, when they say the Lineweaver and Burk gives a more uniform spread of points. However, inspection of a Lineweaver and Burk plot of the same data used above (Fig. 2) shows that this is not the case. Moreover, Dixon and Webb also argue<sup>6</sup> that the position of a straight line is most precisely determined by the points at both ends. It will be seen that such crowding as there is with the Eadie plot occurs towards the two ends, and so this argument favours the Eadie method. The values of the substrate concentration  $s_1, s_2, \dots, s_n$ , which give equal increments ( $\Delta v$ ) of the velocity, starting from the intercept on the  $v/s$  axis, are given by:

$$s_n = \frac{Km}{\frac{V}{n \cdot \Delta v} - 1}$$

The saving in time of plotting enzyme data by the Eadie method outlined here is appreciable for a single set of results. Where a series of measurements is made at various temperatures, for example, and for the same series of substrate concentrations at each temperature, then the saving of time is very great indeed, since all the results can be plotted together. The same considerations also apply to a series of inhibitors measured against the same set of substrate concentrations<sup>9</sup>. A further advantage of this method is that it reduces the tendency to over-emphasize the significance of the values for the lowest substrate concentration, which occurs with the Lineweaver and Burk plot. This is particularly acute in the case of enzymes showing substrate inhibition, where measurements have perforce to be made at very low substrate concentrations. Here one may be working near the limits of the assay methods available, and the percentage error of the lowest velocities may be much greater than those at higher concentrations.

The Eadie plot also offers less temptation to draw a straight line, when there is departure from linearity at the higher substrate concentrations.

The effect of EDTA on glucose-6-phosphatase activity is shown in Fig. 2. There was a reduced rate of hydrolysis of glucose-6-phosphate when 4 mM EDTA was added to the assay system, but, in the presence of 7 mM EDTA, the rate of hydrolysis was not further decreased. This would be expected if part of the hydrolysis observed in the absence of EDTA were due to the action of alkaline phosphatase. When increasing amounts of potassium fluoride were added to assay systems already containing 4 mM EDTA, there was only slight, if any, decrease of the reaction rate, indicating that the hydrolysis of glucose-6-phosphate due to the action of acid phosphatase is very small indeed. A specific assay system for glucose-6-phosphatase should, therefore, include EDTA and potassium fluoride to inhibit alkaline and acid phosphatase respectively and thus allow the determination of the true glucose-6-phosphatase activity.

Under the conditions indicated in the legend of Fig. 2, the hydrolysis of glucose-6-phosphate proceeded linearly with time (up to 20 min of incubation at 37°) and protein

Fig. 1. The effect of EDTA and KF on alkaline (A) and acid (B) phosphatases. Alkaline phosphatase was assayed as follows: in a total volume of 1 ml., 40 mM ethanolamine-HCl buffer, pH 9.5; 40 mM  $\beta$ -glycerophosphate, pH 9.5; and 0.2 mg protein of a mixed brush border and nuclei fraction from cat small intestinal mucosa were incubated for 15 min at 37°. The reaction was stopped by adding 1 ml. of 10 per cent trichloroacetic acid (TCA) and 2 ml. of 5 per cent TCA containing 12.5 g of 'Norit A' per 100 ml. After filtering, an aliquot of the filtrate was assayed for inorganic phosphate<sup>1</sup>. Acid phosphatase was assayed by incubating, in a final volume of 2 ml., 50 mM acetate buffer, pH 5.4; 15 mM  $\beta$ -glycerophosphate, pH 5.4; and 0.8 mg of protein for 15 min at 37°. A mitochondrial fraction from cat small intestinal mucosa suspended in 0.3 M sucrose was used as source of enzyme. Just prior to the assay, the preparation was diluted 1:10 with deionized water and homogenized in a Waring blender for 4 min. The reaction was stopped by adding 0.2 ml. of 50 per cent TCA and 1.8 ml. of 5 per cent TCA containing 12.5 g of 'Norit A' per 100 ml. The determination of inorganic phosphate was carried out as indicated above. EDTA (●—●—●) and KF (■—■—■) were added as indicated. The values quoted were corrected for enzyme and substrate controls

Fig. 2. The effect of EDTA and KF on glucose-6-phosphatase activity. The assay system contained, in a final volume of 0.7 ml., 43 mM maleate buffer, pH 6.0; 28.5 mM glucose-6-phosphate, pH 6.0; and 1.8 mg protein of a microsomal fraction from cat small intestinal mucosa. After incubation at 37° for 15 min, the reaction was stopped by adding 1.3 ml. of 10 per cent TCA and 2 ml. of 5 per cent TCA containing 12.5 g of 'Norit A' per 100 ml. Inorganic phosphate was determined as indicated in Fig. 1. EDTA (●—●—●) was added as indicated and KF (■—■—■) was added as indicated in the presence of 4 mM EDTA. The values quoted were corrected for enzyme and substrate controls

concentration (up to 2  $\mu$ moles of inorganic phosphate liberated per 20 min). In the assay of glucose-6-phosphatase, three tubes should be set up all containing 4 mM EDTA and 2 mM potassium fluoride. The amounts of inorganic phosphate liberated in the absence of substrate and enzyme respectively should be subtracted from that obtained with the complete system.

The experiments quoted so far were all done with particulate preparations from cat small intestinal mucosa but preparations from rabbit or guinea-pig small intestinal mucosa, although not so extensively studied, gave similar results.

### Kinetic Evidence for a Nucleic Acid which regulates RNA Biosynthesis

THE rate of synthesis of nucleic acids in *Escherichia coli* strain B<sub>u</sub> has been examined in a variety of situations by measuring the incorporation into TCA insoluble material of 20-sec pulses of <sup>14</sup>C-8-guanine. In most cases the 20-sec pulses are long enough to give useful amounts of incorporations. However, extensive washing of the 'Millipore' filters must be carried out and frequently long counting times must be used. There is a short lag in the utilization of <sup>14</sup>C-8-guanine, but under most conditions 20 sec gives about half the radioactivity which would have been estimated from the rate of incorporation at later times, that is, there is about 10-13 sec worth of materials in pools already present in the cell, or made before feed-back inhibition becomes effective. Incorporation of radioactivity is the same at 0.1 the external concentration of <sup>14</sup>C-8-guanine as that standardly employed

(5  $\mu$ M), implying that feed-back inhibition is under both conditions maximal and rapid.

When a culture growing slowly ( $\sim 300$ -min doubling time) in 0.2 per cent DL-alanine as carbon source is 'shifted up' by the addition of 0.2 per cent glucose and 0.1 per cent casamino-acids, the rate of RNA synthesis starts to increase in less than 5 sec. The acceleration is constant until the rate achieves that characteristic of the new medium ( $\sim 31$ -min doubling time). This has been observed when vitamins in addition are included, when tryptophan is present throughout, and when chloramphenicol (50  $\mu$ g/ml.) is present in the shift-up medium (Fig. 1). In every case the acceleration is essentially instantaneous and is constant with values ranging from  $46$  to  $51 \times 10^{-13}$  moles  $^{14}\text{C}$ -8-guanine/mg dry weight  $\cdot 20$ -sec pulse  $\cdot$  sec. The rate characteristic of the new medium is achieved in 95–110 sec. From this it follows that new protein synthesis is not required to support the higher rate of RNA synthesis, because of the well-known 3-min lag in the production of new protein and because it occurs in the presence of chloramphenicol. Therefore, there are adequate amounts of RNA polymerase and the enzymes of nucleic acid intermediary metabolism in the slowly growing cells to support the forty-fold increase in the rate of RNA synthesis. In addition, these findings make the new suggestion that no special protein controlling the rate of RNA synthesis need be newly synthesized to increase the rate of RNA synthesis. Although there is doubt about the quantitative relationships, it is clear that messenger, transfer, and ribosomal RNA synthesis contribute significantly to the pulse incorporation in both media. Thus, a good deal of both messenger and ribosomal RNA synthesis (and probably transfer RNA) is controlled in the same rapid fashion, which would suggest a common regulation.

The strain of bacteria used requires uracil, which is normally supplied at 3  $\mu$ g/ml. When the culture is shifted by membrane filtration into medium devoid of uracil, the rate of RNA synthesis progressively decays (Fig. 2). If uracil is included in the radioactive pulse medium (open circles), 20–40 per cent greater rates of incorporation are observed than if uracil is omitted (solid circles). The stimulation of uracil in the pulse medium is a constant percentage increase no matter how long the starvation is protracted, or if the uracil concentration is increased and supplemented with uridine and cytidine. The half-life for the decay of the rate of RNA synthesis is 3.5 min in the experiment shown. Other experiments have shown

Fig. 1. To a culture growing with a doubling time of 320 min in M-9 at  $37^\circ$  with aeration with 0.2 per cent DL-alanine as carbon source at time zero, 0.2 per cent glucose, 0.1 per cent casamino-acids, 1 per cent by volume of a vitamin preparation (MEM) of Microbiological Associates, and 50  $\mu$ g/ml. chloramphenicol were added. The bacterial concentration was  $0.052$  mg/ml. At the times indicated, 1.0 ml. aliquots were added with an automatic syringe to 1.0-ml. medium of the final composition of the culture, except that  $^{14}\text{C}$ -8-guanine (10 mc./mmole) was present. 2.0 ml. of 10 per cent TCA were squirted in after precisely 20 sec. The open circles are controls in which the TCA was added to the radioactive medium before the addition of the bacteria. Note that the pre-shift values do not indicate the rate of RNA synthesis in that medium because of the additional nutrients in the pulse medium.

Fig. 2. A culture (doubling time 35 min) was filtered and resuspended in the pre-warmed rich medium of the same composition, but lacking uracil. Filtration commenced at  $-3$  min. Uracil was added (3  $\mu$ g/ml.) at 8 min. Pulse measurements in medium containing 3  $\mu$ g/ml. uracil (open circles), pulse measurements in medium lacking uracil (closed circles).

that it is not constant but about 1.5 min in the first 2 min after uracil removal, and that it is much slower than 3.5 min after the first 8 min. On the addition of uracil, after the eighth min (Fig. 2), RNA synthesis is accelerated exponentially with a 20-sec doubling time. This exponential type of acceleration has been observed several times including when the cells have been starved of uracil for 1 h. In this case, the doubling time was 30 sec. Because of the decreased counting rates, 1-min pulses were used to get measurable radioactivities.

Necessary controls showed that even with much larger amounts of uracil, together with uridine and cytidine, no faster recovery of RNA synthesis was obtained. Other controls showed that the 20-sec pulse measurements, although approximately proportional to the steady-state rate of guanine incorporation, are not exactly proportional. In fact, the guanine pools are altered by the uracil starvation, but this can only account for a factor of less than two-fold in the exponential acceleration that spans more than a decade (more than two decades in the 1 h uracil starvation experiment). A sham filtration with uracil in the wash and resuspension medium showed that RNA synthesis is not altered by the manipulations employed.

It thus seems necessary to postulate a type of RNA that is rapidly turning over in the cell and the function of which is to stimulate nucleic acid synthesis in general and, specifically, its own synthesis. It could do so by interaction with the polymerase, or by competing with the DNA for the various kinds of repressor molecules. In addition, the synthesis of this special type of RNA would be controlled by the general nutritional level of the cell and we would presume it to be the product of RC locus<sup>1</sup>.

When nutrients are removed (the 'shift down') ribosomal RNA synthesis abruptly ceases, but at least some messenger synthesis continues longer. A similar situation should obtain when an analogue of an amino-acid is added which is a non-utilizable feed-back inhibitor of the normal amino-acid, such as 5-methyl tryptophan.

When  $10^{-5}$ – $10^{-4}$  M DL-5-methyl tryptophan is added to a culture growing in glucose, casein hydrolysate, vitamins, and uracil (doubling time 30 min), the growth abruptly slows

to a doubling time of about 330 min. The rate of RNA synthesis in less than 5 sec commences to decay exponentially with a half-life ranging (in five experiments) from 30 to 38 sec. The same decay constant is observed when the amino-acids and vitamins are removed by membrane filtration. The experiments in this case are technically much more difficult. When large amounts of tryptophan (or the vitamins and amino-acids) are added back after 3–10 min, an induction phase is noted which is consistent with a 20–30 sec doubling time for an autocatalytic process, and it may take 10 min to recover full synthetic rate.

Absolute control of all RNA synthesis cannot be exercised by the autocatalytic control loop and the induction of the *RC* locus above. Neidhardt<sup>2</sup> has shown that relaxed mutants still control their RNA synthesis to give the ribosomal content consonant with growth supporting capabilities of the medium. Similarly, the postulated controlling RNA is not limiting under the conditions of slow growth on alanine as indicated in Fig. 1. As well, a culture starved of its carbon source (uracil present) for 3 h immediately without lag synthesizes RNA at a linearly accelerating rate, similar to the conditions of Fig. 1, when the amino-acids, vitamins, and glucose are added. Thus, it is necessary to postulate an additional control which obviates the influence of the special RNA on its own synthesis. This, of course, requires further investigation, but we have an example (addition of tryptophan to a rich culture treated with 5-DL-methyl tryptophan for 0.5–1 h) which shows an exponential followed by a linear recovery phase.

The only alternative explanation which we have been able to imagine is that RNA synthesis is generally limited by some small molecular weight compound, say a uracil derivative, of which the rate of synthesis is under physiological and genetic control. The exponential build-up shown in Fig. 2 would then simply be indicative of a number of steps from exogenous uracil to this derivative. This appears to us less likely, since the autocatalytic law seems to be obeyed over a large factor and, secondly, because uracil replacement should have the same absolute restoring action on RNA synthesis no matter how long the starvation was protracted. Further, the investigations with 5-methyl tryptophan would require an entirely different explanation.

It also does not appear possible to explain these results on the hypotheses that uncharged transfer RNA molecules act as inhibitors of RNA synthesis generally<sup>3</sup> or as co-repressors for the majority of operons in the cell<sup>4</sup>.

### Isolation of an Unknown Component from Hydrolysates of Elastin

PARTRIDGE *et al.*<sup>1</sup> have described two new polyfunctional amino-acids obtained as products of an acid hydrolysis of bovine elastin. Compounds of identical nature were also obtained by us<sup>2</sup>. These substances, designated desmosine and isodesmosine by Partridge *et al.*, have been shown by these investigators to contain a pyridine nucleus with amino-acid substituents on both carbon and nitrogen atoms of the ring<sup>3</sup>. The special significance of desmosine

and isodesmosine is that they appear to be involved in the cross-linking of polypeptide chains of elastin<sup>1</sup>.

To gain more information about the nature of cross-linking in elastin, we have attempted to isolate peptides from enzymatic hydrolysates of elastin, in which desmosine and isodesmosine are present in large amount. In the course of this work we observed that such peptides indeed can be obtained but that they contain yet another hitherto undescribed ninhydrin-positive substance, designated by us as  $X_4$ .

For the isolation of peptides, 100 mg of elastin suspended in 10 ml. of 0.1 M potassium carbonate-hydrochloric acid buffer, pH 8.9, was digested by addition of 1 mg of either elastase, nagarse or papain. Following overnight incubation at 38° C, the digests were acidified with hydrochloric acid and placed on columns of 'Dowex 50-X2'. Elution was started with 0.2 N citrate buffer, pH 3.1, followed by 1.1 N citrate buffer and 2.1 N citrate buffer, both at pH 5.1. Then, 500 ml. of water was passed through the column and final elution was carried out with 0.05 N sodium hydroxide. By this procedure, the peptides enriched in desmosine, isodesmosine and  $X_4$  were eluted with 0.05 N sodium hydroxide. All the enzymatic digestions investigated yielded a similar fraction. This fraction accounted for 2–4 per cent of the ninhydrin-positive material and approximately 35–48 per cent of the 275 mμ absorbing material placed originally on the column.

The amino-acid composition<sup>4</sup> (Technicon analyser) of the desmosine-isodesmosine rich fraction obtained after digestion with either elastase, papain or nagarse is given in Table 1. The amino-acid analysis of bovine elastin before treatment with enzyme is also given in Table 1. Isodesmosine and desmosine, in these analyses, appear in eluate fractions 18 ml. and 28 ml. respectively after those containing ammonia.  $X_4$  appears in fractions 13 ml. before those containing lysine and, if ornithine is also present, between ornithine and lysine. It should be emphasized that residues of desmosine and isodesmosine are calculated using a ninhydrin colour equivalent equal to four times that of leucine. On the other hand, in view of our lack of knowledge of the structure of  $X_4$ , residues of this substance are calculated using a colour equivalent equal to that of leucine. It may be seen that the peptide fraction relatively rich in desmosine and isodesmosine is also rich in  $X_4$ .

Table 1. AMINO-ACID COMPOSITION OF PEPTIDE FRACTIONS RICH IN DESMOSINE, ISODESMOSINE AND  $X_4$ \*  
(Expressed as residues per 1,000 residues)

Amino-acid	Bovine elastin	Elastase	Papain	Nagarse
Cystic acid	3.2	13.7	12.2	13.8
Hydroxyproline	7.1	7.7	6.1	Trace
Aspartic acid	7.0	7.3	10.3	12.3

Desmosine	1.7	9.1	5.1	11.1
$X_4$	1.8	6.1	4.8	7.7

\* Values are uncorrected for slight losses during hydrolysis.

Desmosine, isodesmosine and  $X_4$  were isolated in the following manner. 15.6 g of elastin of bovine ligamentum nuchae was hydrolysed in 6.0 N hydrochloric acid under reflux for 24 h. The hydrolysate was evaporated to dryness, redissolved in water and placed on a 'Dowex 50-X8' column of dimensions 4.5 cm × 17 cm. Elution was carried out with 1 l. of 1.5 N hydrochloric acid, followed with 5 l. of 2.5 N hydrochloric acid, and finally with 6 l. of 4.0 N hydrochloric acid. The resulting chromatogram is

shown in Fig. 1. Fractions 320–350 were pooled, and the combined fraction was evaporated to dryness. Most of the reactivity of this fraction with ninhydrin was due to the presence of  $X_4$ . The latter was further purified by dividing the eluant stream coming from the column on the Technicon amino-acid analyser. The fractions containing  $X_4$ , obtained in this manner, were pooled, acidified to pH 2 with hydrochloric acid, and desalted on a 'Dowex 50' column utilizing 0.25 N ammonium hydroxide as the eluting solvent. The  $X_4$  fractions obtained by this procedure were evaporated to dryness, washed with ethanol and finally with ether. Re-chromatography of the purified material resulted in emergence of only one peak; this corresponded to  $X_4$ . Paper chromatography in *n*-butanol-acetic acid-water (4:1:5) revealed only one ninhydrin-positive spot with an  $R_F$  of 0.13.

$X_4$  does not exhibit absorption of visible light nor, in contrast to the desmosines, of ultra-violet light. It has an infra-red spectrum characteristic of an amino-acid; the compound showed absorption maxima for ionized carboxyl at 1,600  $\text{cm}^{-1}$  (asymmetrical) and 1,415  $\text{cm}^{-1}$  (symmetrical) and amino-acid I and II bands (deformation frequencies) at 1,635  $\text{cm}^{-1}$  and 1,510  $\text{cm}^{-1}$ . The hydrochloride of  $X_4$  revealed an absorption maximum for unionized carboxyl at 1,740  $\text{cm}^{-1}$ . The spectrum also suggests the presence of a hydroxyl group, but the evidence is not conclusive. There is no indication of the presence of ketone, aldehyde or lactone functions. Elemental analysis, kindly performed by the F. and M. Scientific Co., Avondale, Pa., using their Model 180 carbon-hydrogen-nitrogen analyser, showed: C, 44.7; H, 7.1; N, 10.4 per cent. This corresponds to an empirical formula of  $\text{C}_6\text{H}_{10}\text{NO}_3$ . High-voltage electrophoresis of  $X_4$  at either pH 6.4 or pH 3.4, using pyridine-acetate buffers, revealed only one ninhydrin-positive component. In 30 min at 3,500 V,  $X_4$  migrated 7.0 cm towards the negative pole at pH 3.4 and 6.2 cm towards the negative pole at pH 6.4.

Without special prejudice, the authors consider that any of four possible relationships of  $X_4$  to the original elastin may account for its ultimate appearance in hydrolysates of that protein prepared with acid. These possibilities are: (1)  $X_4$  is a hitherto undescribed amino-acid present in the polypeptide backbone *per se* of elastin molecules. (2)  $X_4$  is a discrete amino-acid involved in the cross-linking of several polypeptide chains of elastin. (3)  $X_4$ , together with desmosine and isodesmosine, are degradation products of the true cross-linking substance present in elastin before hydrolysis with acid. (4)  $X_4$  is a

degradation product of another substance unrelated to the desmosines.

At present, investigations are under way to determine which of these possibilities actually applies, and to determine the precise structure of  $X_4$ .

### Relation between Serum and Colostrum Antibody in the Goat

It has been suggested that antibody synthesis can occur in mammary tissue<sup>1</sup>. It has also been suggested that the observed differences in  $\gamma$ -globulins and in specific antibodies between serum and milk or colostrum are due to selectivity or to active transport mechanisms<sup>2,3</sup>. On the other hand, Hanson<sup>4</sup> was unable to identify a milk protein antigenetically identical to human serum 7S  $\gamma$ -globulin, and Chodirker *et al.*<sup>5</sup> were able to demonstrate little or no  $\gamma_2$ -globulin in milk. Much of this work was based on the measurement of antibody activity without actual isolation of the antibody, or on  $\gamma$ -globulin determination by some means unrelated to the presence of specific antibody. Using labelling techniques, Askonas *et al.*<sup>6</sup> showed that in the rabbit, and probably in the goat also, specific antibodies in the milk appeared to be derived directly from serum antibody. The work recorded here was undertaken to compare the electrophoretic mobility in starch gel of a particular antibody from the serum of the goat with that from colostrum, both of which were free of non-specific protein. The electrophoretic patterns of the papain digests of the respective antigen-antibody precipitates were also compared.

A normal female goat was immunized with bovine serum albumin (Armour) in complete Freund's adjuvant by weekly subcutaneous injections. Blood was obtained from the jugular vein and colostrum by usual milking techniques. A quantitative precipitin curve was obtained using the 40 per cent ammonium sulphate fraction of the goat serum, and the proportions at equivalence were determined. Freshly obtained colostrum was centrifuged at 4,500 r.p.m., 2° C for 60 min. The fatty layer was removed and the supernatant poured off. The pH of the supernatant was lowered to 4.5 by the addition of concentrated HCl with constant mixing; the precipitate which formed was centrifuged off, and the pH of the supernatant restored to 6.5 with NaOH<sup>7</sup>. Precipitin tests were then performed both with this material directly and with the 40 per cent ammonium sulphate fraction.

The immune precipitates formed at equivalence from serum and colostrum were washed four times with 0.9 per cent NaCl at 2° C, then dissociated by treatment with glycine-sulphuric acid buffer<sup>8</sup>, pH 2.5, or digested by crystallized papain<sup>9</sup> in 0.1 M sodium phosphate buffer containing 0.01 M

Fig. 1. Chromatogram of an acid hydrolysate of elastin from bovine ligamentum nuchae eluted from 'Dowex-50'. The flow rate of elution was approximately 2 ml./min, and fractions of 18–20 ml. each were collected. The ultra-violet absorption spectrum and content of amino groups (ninhydrin) were determined on every third fraction.

Fig. 1. Starch-gel electrophoresis in glycine-sulphuric acid buffer, pH 2.5. Anode situated on the right and direction of migration from right to left. (a) Goat serum, ammonium sulphate fraction; (b) goat serum, dissociated antigen-antibody precipitate; (c) goat colostrum, dissociated antigen-antibody precipitate. The most rapidly moving band was a goat albumin contaminant in (a), and bovine serum albumin in (b) and (c). The middle band was 7S  $\gamma$ -globulin in (a), and antibody in (b) and (c). The slow band in all three was not identified.

Fig. 2. Starch-gel electrophoresis of papain-digested antigen-antibody precipitates derived from: (a) goat serum; (b) goat colostrum; (c) rabbit serum. Procedure as in Fig. 1. The notches in the side of the gels indicate the location of the fluorescein-labelled antigen or its derivative.

EDTA and 0.01 M cysteine for 2 h. The digests were then dialysed against water and lyophilized.

Two mg of each immune precipitate in glycine-sulphuric acid buffer, ionic strength 0.25, were electrophoresed in starch gel<sup>10</sup> using the same buffer in the electrode compartments and an eight-fold dilution for the gel. A constant current of 40 or 50 m.amp was applied for 16–20 h at 4° C, following which the gel was cut horizontally, one half stained with amido-black and decolorized in the usual manner. The bands representing antibody coincided exactly with each other and with goat serum  $\gamma_2$ -globulin (Fig. 1). The papain digests of the respective antigen-antibody precipitates were electrophoresed under the same conditions and the resulting bands also corresponded exactly (Fig. 2). For comparison, papain digests of antigen-antibody precipitates derived from rabbit anti-bovine serum albumin are also shown. The pattern of the latter is entirely different.

Fluorescein isothiocyanate (General Biochemicals) was coupled to bovine serum albumin<sup>11</sup> and the unbound dye removed by passage of the mixture over a 'Sephadex G 25' column equilibrated with 0.9 per cent NaCl. No significant reduction in precipitation with antibody was noted. Papain digests of the antigen-antibody precipitates were prepared from fluorescein-labelled antigen and antibody derived from both serum and colostrum. After electrophoresis in starch gel, the unstained halves of the gel were examined with long-wave ultra-violet light. The fluorescent bands were observed to coincide and their location was indicated by notches made on the stained

portions of the gels (Fig. 2). With digested rabbit precipitate the fluorescent band occupied a different position. Further investigations on the relation between rabbit and goat antibody will be presented elsewhere.

'Sephadex G 100' chromatography in 0.9 per cent NaCl of the papain digests of each of the serum and colostrum goat antigen-antibody precipitates showed two well-separated peaks in the same position in each case. When the fluoresceinated antigen was used the fluorescence was confined to the first peak in both instances. In addition, lines of identity were observed in agar gel between bovine serum albumin on one hand and serum and colostrum on the other.

## PHYSIOLOGY

### Fasting Levels of Growth Hormone in Men and Women

RECENT methodological improvements in radio-immunoassays for growth hormone<sup>1,2</sup> have led to increasing use of these techniques in clinical and physiological research. We have found a large and apparently previously unreported difference in the fasting growth hormone level of normal males and females.

Fifteen healthy, non-obese male volunteers, averaging 32 years of age (19–54 years), and 8 similarly healthy, non-obese, non-pregnant females, averaging 41 years of age (30–62 years), were assembled. All had a normal glucose tolerance by the criteria of Fajans and Conn<sup>3</sup>, and gave a negative family history of diabetes. After a 3-day high carbohydrate diet and an overnight fast, a fasting blood specimen was obtained and assayed for growth hormone by the radio-immunoassay technique of Roth, Glick, Yalow and Berson<sup>2</sup>. All specimens were assayed in duplicate. Neither the duration of the overnight fast nor the amount of physical exercise before the test was measured.

The mean growth hormone concentration of the females greatly exceeded that of males, averaging 4.91  $\mu\text{g}/\text{ml}$ . ( $S.D. \pm 3.32$ ) with a range of from 0.9 to 10.6  $\mu\text{g}/\text{ml}$ . The mean level in men was 0.27  $\mu\text{g}/\text{ml}$ . ( $S.D. \pm 0.14$ ) with a range of from 0.1–0.7  $\mu\text{g}/\text{ml}$ . This difference is statistically significant ( $P < 0.05$ ). Fig. 1 shows the mean pattern of growth hormone concentration noted before and during a 100-g oral glucose tolerance test in the two groups, and reveals the persistence of the inter-group difference until at least 40 min after glucose ingestion.

The mean fasting plasma glucose concentration, as determined by the method of Hoffman<sup>4</sup> on the Technicon Autoanalyser, was 94 mg per cent (89–104) in the female

Fig. 1. Growth hormone concentrations before and during a 100 g oral glucose tolerance test in 8 normal non-obese females and 15 comparable males. The higher fasting growth hormone level of the female group persists until at least 40 min after glucose ingestion. No significant inter-group differences are noted after the 60-min point.

group and 99 mg per cent (72–111) in the male group. Neither this difference nor the age difference between groups adequately explains the difference in growth hormone levels, since their elimination by regrouping of subjects fails to diminish the difference in growth hormone.

Examination of some earlier data tends to support these findings. Hunter and Greenwood<sup>5</sup> measured fasting growth hormone levels in 6 men and 4 women, 3 of whom were obese; despite this dissimilarity in their subjects, qualitatively similar sex differences in growth hormone concentration can be calculated from their data.

Although the physiological implications of this sex difference remain to be determined, it is apparent that it should be taken into consideration in investigations of human growth hormone concentrations.

## A Charge-transfer Complex between Procaine and Ribonucleic Acid

An understanding of the mechanism of action of local anaesthetics is of great importance for the molecular physiology of nerve. An intense colour reaction between the local anaesthetic procaine (*p*-aminobenzoyldiethylaminoethanol) and ribonucleic acid (RNA) has been discovered. The active nucleic acid components is apparently ribose. The pentose sugars xylose and arabinose are also active. There is no reaction with deoxyribose or with DNA. Hydrolysates of RNA produced by the hydrochloric acid or perchloric acid method are both active.

The method of obtaining the reaction with RNA is very simple and is as follows: 200 mg of commercial

Fig. 1. Charge-transfer bands of procaine-RNA complex. RNA hydrochloric acid hydrolysate. Absorption spectra recorded with an automatic recording spectrophotometer at 1-min intervals: upper curve, at 1 min; middle, at 2 min; lower, at 3 min. Ambient temperature 25° C.

yeast RNA and 200 mg of procaine hydrochloride are placed in a dry test-tube with 3 ml. of distilled water and the test-tube is shaken gently. Within 1–2 min the RNA mass turns a brilliant magenta colour ( $\lambda_{\text{max}} = 550 \text{ m}\mu$ ). At room temperature this colour is transient and rapidly begins to fade and to be replaced by browning probably due to furfural formation. However, if the magenta complex is frozen at 0° C the absorption band at 550 mμ may remain stable for several months.

A similar sequence of events occurs with yeast RNA hydrochloric acid hydrolysate (Fig. 1) after clarification by passage through a 0.22-μ 'Millipore' filter. In contrast with RNA and RNA hydrolysate, the reaction with D-ribose requires several hours and evidently does not occur above pH 3–4. There is no reaction with any of the nucleic acid bases nor with phosphoric acid.

In a series of reports<sup>1–3</sup> Eckert has attempted to demonstrate that procaine can enter into a charge-transfer complex with various electron-acceptor compounds, including thiamine, and he has suggested that it is a  $\pi$ -electron or charge-transfer complex with thiamine which is responsible for the anaesthetic action of the drug. Two recent authoritative reviews<sup>4,5</sup> have directed attention to these experiments and to the intriguing possibility that a charge-transfer reaction is involved in certain classes of anaesthetic action. I have repeated Eckert's experiments with procaine. His 'charge-transfer' bands are actually artefacts produced by his method of spectrophotometric analysis. They are difference bands and unrelated to his conclusions.

The essential result of a charge-transfer complex is the appearance of a new intense absorption band, usually at a longer wave-length, where neither compound has any significant absorption. Such a complex belongs to the class of weak interactions and has a negative temperature coefficient. Many  $\pi$ -electron complexes can therefore be produced only at dry-ice temperatures and their stability is extremely sensitive to any thermal changes. The molecular structure of each member of the complex must be such as to allow for a degree of electron delocalization.

If this requirement is satisfied, then the appearance of a new temperature sensitive absorption band is sufficient evidence for the existence of charge-transfer.

The magenta complex between procaine and certain pentose sugars may be an intermediate stage in Schiff base formation. Procaine is a primary aromatic amine and these sugars possess a free aldehyde group. Such a reaction is the basis for several nucleic acid colour tests. The magenta complex reported here, however, is obtained at room temperature and is transient. It suggests that cell-surface mucopolysaccharides may play an important part in the action of certain anaesthetics, and that a detailed examination of the interaction of polysaccharides with neurotropic primary aromatic amines may prove rewarding.

### Urinary $\beta$ -Amino Isobutyric Acid in the Mouse: Elimination after Intravenous Administration of Deoxyribonucleic Acid

THE initial catabolism of DNA injected intravenously into higher mammals is under the control of the neutral DNases of blood plasma<sup>1</sup>.

This communication concerns the final steps of DNA catabolism followed by the urinary elimination of  $\beta$ -amino-isobutyric acid (BAIBA), an essential catabolite of thymine<sup>2</sup>, after intravenous administration of isologous tritiated DNA. Mice are very useful for such an investigation, since the plasma DNase activity varies in a narrow range for animals in each strain, but notably differs from one strain to another<sup>3</sup>.

Male and female mice, weighing 20–21 g (*C<sub>3</sub>H*) or 17–18 g (XLII) and 3–4 months old, were used. Urine was collected either with the aid of a metabolism cage containing 10 mice or by direct sample-taking. The extraction and the quantitative determination of the BAIBA in the urine were carried out according to a technique based on that of Gerber *et al.*<sup>4</sup>; the determination of the DNase activity of the plasma (pH = 7.5) was carried out according to the technique of Kurnick<sup>5</sup>, applied as a micromethod to mixtures of plasma from the various groups of animals and expressed as Kurnick Units (KU). The sodium in the urine was quantitatively determined by flame spectrophotometry.

The radioactive DNA was extracted from the intestine of the *C<sub>3</sub>H* and XLII mice, using the method of Kay *et al.*<sup>6</sup>, 3 h after intravenous injection of 20  $\mu$ c. of tritiated thymidine labelled in the 5-methyl group. These DNA samples showed the usual optical (spectrum and hyperchromicity in ultra-violet light), physical (light diffusion, viscosity, CsCl gradient density) and chemical (guanine, cytosine, RNA, protein and water contents) characteristics; their specific activities were very similar—of the order of  $2.5 \times 10^5$  d.p.m./mg DNA—as measured in a Packard scintillation counter, all the corrections of quenching being carried out after addition of standard labelled thymidine; DNA was quantitatively determined by the method of Burton; paper chromatography of the bases obtained after perchloric hydrolysis showed that all radioactivity was localized in the thymine; no radioactive contaminant was present (CsCl gradient and successive re-precipitations in alcohol).

In the initial series of experiments, the labelled isologous DNA was injected into one of the tail veins by a perfusion lasting 30 min (0.5 ml. of 0.14 M NaCl containing 1.7–2.0 mg/ml.). In a second series of experiments, a solution of DNA from *C<sub>3</sub>H* and XLII mice was mixed in equal parts and hydrolysed by pancreatic DNase (Worthington) at 37° for 1 h with 0.02 M MgSO<sub>4</sub>.

The values of physiological urinary excretion of endogenous BAIBA were twice as high in the XLII mice as in the *C<sub>3</sub>H* mice, while the volumes of the urine were of the same order (Table 1); this ratio was always found, whether the excretion was expressed in terms of concentration ( $\mu$ moles/ml.) or in absolute value ( $\mu$ moles/24 h). Although the urine samples were taken at random times, the possibility of large fluctuations in diuresis is excluded by the constant urinary sodium values found during the experiments ( $166 \pm 50$  m.equiv. per thousand in *C<sub>3</sub>H* mice;  $170 \pm 37$  m.equiv. per thousand in XLII mice).

Table 1. LEVELS OF THE ENDOGENOUS URINARY BAIBA IN *C<sub>3</sub>H* AND XLII MICE

	Random times urine <i>C<sub>3</sub>H</i>	Random times urine XLII	24-h urine <i>C<sub>3</sub>H</i>	24-h urine XLII
No. of experiments*	25	20	15	7
BAIBA ( $\mu$ mole/ml.)	0.40 $\pm$ 0.14	1.03 $\pm$ 0.35	0.53 $\pm$ 0.17	1.25 $\pm$ 0.57
Mean urinary volume (ml. per 24 h)			5.7	5.3
BAIBA ( $\mu$ mole/24 h)				
Extrapolated	2.28	5.45		
Measured			2.51 $\pm$ 0.65	5.39 $\pm$ 1.56

\* All the determinations have been carried out with a mixture of the urine from a group of ten animals.

After intravenous administration of comparable quantities of isologous labelled DNA, the rate of urinary excretion of labelled BAIBA resulting from the catabolism of this DNA also showed a two-fold difference between the *C<sub>3</sub>H* and the XLII mice (Fig. 1A). Furthermore, after injection of a quantity of hydrolysed labelled DNA corresponding to the dose of DNA used earlier, the rate of excretion of labelled BAIBA was increased in the two strains of mice; the quantities of labelled amino-acids excreted with the urine were always in a proportion of about 1/2 (Fig. 1B).

Since the same ratio (1/2) is found between the plasma DNase activities in *C<sub>3</sub>H* (0.14–0.23 KU) and XLII mice (0.28–0.39 KU) enzymatic activity and BAIBA elimination were determined on the same animals.

A direct correlation between plasma enzyme-level and endogenous urinary BAIBA excretion was found between the two strains (Fig. 2A); moreover, such a correlation holds in each strain between the plasma DNase activity and the speed of tritiated BAIBA elimination (Fig. 2B). These findings are statistically significant at the 1 per cent (*C<sub>3</sub>H*) and 5 per cent (XLII) level.

Fig. 1. Tritiated BAIBA urinary excretion after intravenous injection of isologous tritiated DNA. A, polymerized tritiated DNA; B, hydrolysed tritiated DNA. Each curve records five mice. ---, XLII; —, *C<sub>3</sub>H*.

Fig. 2. Relationship between neutral plasma DNase activity and BAIBA urinary excretion. A, endogenous BAIBA (10 mice for each point); B, radioactive BAIBA 3 h after intravenous injection of tritiated DNA (5 mice for each point). x, XLII;  $\Delta$ , C<sub>3</sub>H

These results lead to three main conclusions:

(1) BAIBA is a catabolite of DNA thymine; nevertheless it can only account for a small fraction of it (5–10 per cent). Thymine may take other metabolic pathways or perhaps BAIBA itself may undergo catabolic degradation.

(2) Though the DNase activity of plasma regulates the initial degradation of intravenously injected DNA (ref. 1), it does not determine all the transformations from DNA thymine to BAIBA. These transformations are controlled by many other enzymes the activities of which are regulated at levels near those of neutral plasma DNases, but differing from one strain to the other.

(3) The rate of BAIBA elimination in urine depends on the intensity of exogenous DNA catabolism and affords a possible means of expressing it.

On the other hand, these results suggest that this conclusion might be extended to normal elimination of BAIBA which could be an index of the intensity of cell DNA degradation, and so would give a criterion for an easy biochemical evaluation of cellular turnover. This elimination is probably, as in man<sup>3</sup>, under genetic control, and its variations are not due to renal influences, since preliminary results show that the plasma-level of BAIBA is higher in XLII than in C<sub>3</sub>H strain mice.

### Dilution of the Diet and Feed Intake in the Mouse

Mice were fed from 3 to 6 weeks of age (weaning to mating) on diets made up by diluting a normal diet with different levels of an indigestible filler (cellulose). A greater range of diets, and younger animals, were used than in earlier work<sup>1</sup>. The error (and labour) associated with separating waste feed and faeces when feeding pelleted food was overcome by feeding ground diets, so that waste feed could be sieved from the faeces.

The animals used in the present experiments were from a random bred strain previously fed normally. The

change to each experimental diet was made abruptly after normal weaning at 3 weeks of age. The diets used are denoted by the percentage dilution with cellulose of the normal diet.

**Experiment 1.** The mice used in this experiment were litter mates from litters adjusted to 4 of each sex at birth. Only those of one sex from each litter were used on each diet. Data were from 4 litter mates per cage and 3 cages of each sex per diet (Table 1).

Table 1. WEIGHT GAIN AND FEED INTAKE FROM 3 TO 6 WEEKS

Sex	Diet dilution (%)	No.	Gain/head/day (g)	Dry matter intake/head/day (g)	Dry matter intake (g)/gain (g)	Gut wt. (g)/body wt. (g)
M	—	12	0.67	3.82	5.70	0.16
	30	12	0.73	5.64	7.73	0.19
	50	12	0.66	7.70	11.67	0.23
	70	8	0.06	5.94	99.01	0.31
F	—	12	0.44	3.76	8.55	0.16
	30	12	0.48	5.35	11.15	0.19
	50	12	0.51	6.98	13.69	0.24
	70	—	—	—	—	—

The mice on the 70 per cent diluted diet had difficulty in dealing with this diet in the ground form. The same diet in the pelleted form was fed successfully to similar mice in the laboratory. All the female mice on this diet died and the 8 male survivors gained so little weight that the intake per g of gain was exaggerated.

Mice were killed at 6 weeks of age and the fresh weight of the intestinal tract was recorded. This clearly reflected the compensatory 'gut-fill' of the animals on the highly diluted diets.

The dry-matter intake per head per day was doubled on the 50 per cent diluted diet, and then dropped in the males at the higher level of dilution.

**Experiment 2.** In this experiment males only were used. Litters which had been adjusted to 4 mice of each sex at birth were bulked at weaning, and then randomized to each treatment. This was simpler, but gave results as reliable as the method in exp. 1. Data were from 4 mice per cage with 6 cages per diet (Table 2).

Table 2. WEIGHT GAIN AND FEED INTAKE FROM 3 TO 6 WEEKS

Sex	Diet dilution (%)	No.	Gain/head/day (g)	Dry matter intake/head/day (g)	Dry matter intake (g)/gain (g)	Gut wt. (g)/body wt. (g)
M	—	24	0.81	3.95	4.88	0.16
	30	24	0.68	4.99	7.34	0.18
	50	24	0.60	6.34	10.57	0.22
	70	16	0.48	4.16	8.67	0.30

As in exp. 1, dry matter intake per head per day increased up to a dilution of 50 per cent and then declined. This is similarly reflected in intake per g of gain, and the response to dilution is also shown in the 'gut-fill' of the animals on each treatment.

It is apparent that the compensation mechanism of the animal breaks down after about 50 per cent dilution. The 70 per cent diluted diet again caused the death of some animals. Up to a dilution of 50 per cent the mice appeared normal, but at 70 per cent dilution they were under stress.

It can be concluded that dilution of the diet brings about a definite compensatory response by the animal, increasing the total dry-matter intake. This takes place immediately after weaning and breaks down at levels of dilution about 50 per cent. Further work is required to investigate the efficiency of utilization of the digested nutrients of the diets, to measure the true effect of the increased intake on the animal.

Before dietary dilution can be used in animals as a means of controlling nutrient intake, the compensation response of the animal, and the effect which increased intake has on digestibility of the diet, must be known over a wide range of dilutions.

# Changes in Sino-atrial Node Transmembrane Potentials on Vagal Stimulation of the Isolated Rabbit Atrium

Hutter and Trautwein<sup>1</sup> reported that vagal stimulation results in hyperpolarization, complete disappearance of action potentials, and a shortening of duration of the post-stimulation pacemaker potentials of the frog sinus venosus. No report has appeared regarding the effects of stimulation of external vagal fibres on sino-atrial (S-A) node action potentials of mammalian heart. In the experiments described here, we set out to test the responses of the various types of S-A node fibres<sup>2</sup> to vagal stimulation of isolated rabbit atria.

Albino rabbits, weighing 1.5–2.0 kg, were used for making the isolated vagus-atrial preparation following the technique described by Toda *et al.*<sup>3</sup>. Ringer-Locke solution of the following composition in mmole/l. was used: NaCl, 147; KCl, 5.4; NaHCO<sub>3</sub>, 14.9; CaCl<sub>2</sub>, 2.2; and dextrose, 5.6. The solution was gassed with 95 per cent oxygen–5 per cent carbon dioxide. The temperature of the muscle chamber was maintained at 30° C. Transmembrane action potentials were recorded with the aid of the floating glass microelectrode<sup>4</sup>. An external bipolar electrode was used to record simultaneously from the atrial roof. Both vagi were brought above the surface of the solution for stimulation by a train of rectangular pulses 5–10 V in strength, 1.0 msec in duration, applied at 20/sec.

In the normal solution, vagal stimulation produced bradycardia but not asystole. Marked hyperpolarization, depression of action potential amplitude and shortening of duration in some of the S-A node action potentials occurred concomitantly with the effect on the rate. In other recordings, only slight or no change in action potential configuration occurred despite the appearance of bradycardia. Thus, the S-A node was divided into 4 parts as suggested by the pattern of response to vagal stimulation. Table 1 characterizes the types of action

Table 1. PARAMETERS OF S-A NODE ACTION POTENTIAL CONFIGURATION AND THE CHANGES INDUCED BY VAGAL STIMULATION

Parameter	Characteristics of action potential types			
	Type 1	Type 2	Type 3	Type 4
<i>N</i>	9	24	34	26
<i>MDP</i> (mV)	61.1 ± 1.62	56.3 ± 1.18	55.3 ± 0.66	65.0 ± 0.88
<i>APA</i> (mV)	71.1 ± 1.82	59.7 ± 1.47	58.6 ± 0.81	73.7 ± 1.25
<i>OS</i> (mV)	8.3 ± 0.84	3.9 ± 0.86	4.5 ± 0.48	9.3 ± 0.58
<i>SD</i>	Slight or none	Moderate	Marked	Slight
<i>SD to AP</i>	Sharp	Smooth or sharp	Smooth	Sharp
Changes on vagal stimulation				
Depression of <i>APA</i>	Marked	Marked	Slight	Slight
Hyperpolarization (mV)	7.9 ± 1.07	6.8 ± 0.62	3.0 ± 0.39	1.5 ± 0.35
Reduction of <i>APD</i>	Marked	None*	Slight	Slight or none
Change in <i>SD</i>	—	Decreased	Decreased	No change

The data presented represent mean values ± S.E. of the mean.

potentials and the changes in configuration resulting from vagal stimulation.

Type 1 action potentials were recorded from the septal branch of the S-A ring bundle and close to the superior vena cava. The configuration of these fibres was markedly altered by vagal stimulation as shown in Fig. 1A. After termination of the vagal stimulation, the changes in membrane polarization and in repolarization velocity reversed earlier than the change in action potential amplitude.

Type 2 action potentials were found in the S-A node near the superior vena cava, near the area from which type 3 potentials were recorded, as described below. Type 2 action potentials (Fig. 1B) closely resembled the configuration of the so-called true pacemaker potentials, but the action potentials were sometimes preceded by the simultaneously recorded atrial activity. In response to vagal stimulation, type 2 potentials were markedly depressed

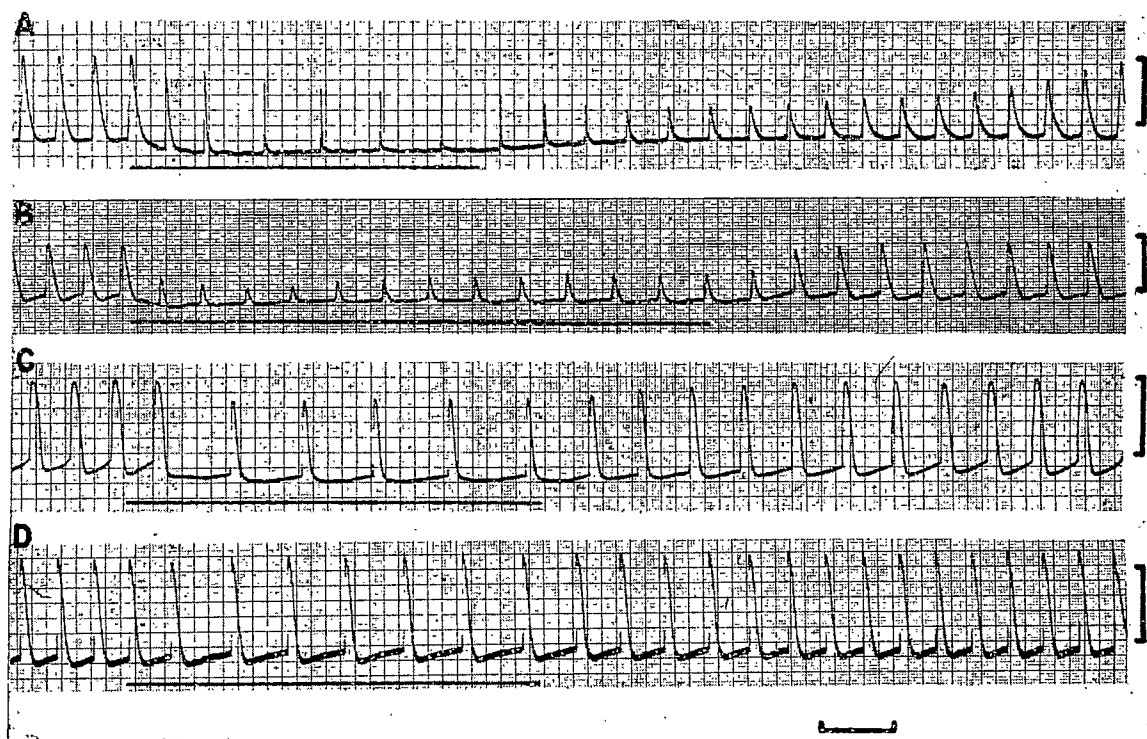

Fig. 1. Variations in response of S-A node action potentials to vagal stimulation. A, B, C and D in the figure represent Type 1, 2, 3 and 4 action potential respectively and responsiveness to vagal stimulation described in the text. Horizontal lines just below each tracing illustrate the period of vagal stimulation. Vertical lines in the right side show the 50 mV calibration and 0 level. Time scale at the bottom: 1 sec

Fig. 2. Effects of vagal stimulation in a solution containing 74 mM Na<sup>+</sup>. Upper tracing represents the external recording of the atrial activity. Lower tracing shows transmembrane potentials of a Type 3 fibre. Horizontal line just below the lower tracing shows the vagal stimulation. Voltage calibration and time scale represent 50 mV and 1 sec, respectively

without a concomitant change in repolarization velocity, in contrast to type 1 potentials. In type 2 fibres, a step on the upstroke and a split on the peak of the action potential were often observed during recovery from vagal stimulation.

Type 3 action potentials were recorded from a part of the S-A node near the crista terminalis. Type 3 potentials always preceded the simultaneously recorded atrial excitation. Vagal stimulation decreased the slope of slow depolarization, resulting in a sharp transition from slow depolarization to upstroke; slight depression of the amplitude of these action potentials with little or no hyperpolarization accompanied the bradycardia (Fig. 1C). Type 4 action potentials were recorded from fibres of the S-A ring bundle close to the crista terminalis and appeared to be transitional fibres.

Type 4 potentials responded to vagal stimulation with a slight decrease in action potential amplitude and duration without change in slow depolarization slope (Fig. 1D). In contrast, atrial fibres responded to vagal stimulation with a slight hyperpolarization (5 mV at most), depression of amplitude (10–20 mV) and marked acceleration of repolarization velocity.

In each preparation, the most prominent configurational change in response to vagal stimulation occurred in parts of the S-A node near the superior vena cava and the interatrial septum. This may be due to the different distribution of vagal innervation in each part of the S-A node or the difference of the permeability increase to potassium ions in the presence of acetylcholine released from vagal terminals.

When the concentration of external potassium was increased (up to 16.2 mmole/l.) the maximal diastolic potential in all S-A node cells was reduced. Bradycardia resulting from vagal stimulation was similar to that observed in the normal solution, but hyperpolarization, particularly in types 1 and 2 action potentials, was markedly reduced in the presence of increased potassium concentration.

In the presence of reduced external potassium concentration (1.35 mmole/l.), the effects of vagal stimulation were augmented, both in the S-A node and in the right atrium. Hyperpolarization in S-A node fibres in response to vagal stimulation was much more pronounced than in the normal solution.

In some experiments, sodium chloride was reduced to 74 mmole/l. with the change in osmolarity balanced by sucrose. The effects of vagal stimulation were greatly augmented in the presence of diminished sodium concentration. Fig. 2 illustrates the marked vagal effects on a type 3 action potential in 74 mmole/l. sodium solution. Marked hyperpolarization (15 mV) and complete disappearance of action potentials occurred during the period of stimulation. In the normal solution, this type of pacemaker fibre responded by slight hyperpolarization (5 mV), decrease in action potential amplitude and duration, and moderate bradycardia during vagal stimulation.

While marked hyperpolarization and shortening in duration were observed in the pacemaker potentials of frog heart<sup>1</sup> in response to vagal stimulation, very little or no change in polarization and the configuration of pacemaker potential (type 3) occurred in the rabbit heart in the normal solution. Because the type 3 pacemaker potential appears to represent the activity of functionally 'true pacemaker' fibres, our results suggest that the cholinergic effect on the slope of diastolic depolarization is of primary significance to atrial rate in the rabbit; hyperpolarization and action potential depression are of lesser significance. On the other hand, in low sodium solution, changes in polarization and in duration similar to those in frog heart were recorded following stimulation of vagi to rabbit heart.

### Metabolic Acetylation by the Mucosal Membrane of the Gastro-intestinal Tract

THE mucosal membrane of the gastro-intestinal tract has been shown to possess considerable capacity for detoxication reactions<sup>1-5</sup>.

On the basis of earlier observations concerning the metabolic acetylation which occurs in the liver and kidney, we have conducted investigations to ascertain whether acetylation occurs also in the different parts of the gastro-intestinal tract. Acetylation is known to take place according to the following reaction:

The foregoing reaction has been found to occur in the liver and kidney of most mammals and birds. The liver especially has proved to be an organ with a very great acetylation capacity. Conditions with high ATP- and coenzyme A-concentrations have also proved favourable in the liver.

The *in vitro* technique was used to examine acetylation in the gastro-intestinal tract. The tissues to be examined were removed from the animal and placed in cooled Krebs-Ringer phosphate solution (pH 7.4). Next, the tissues were cut into pieces about 3 mm in diameter and

transferred to substrate solution of about  $+4^{\circ}\text{C}$ . The composition of the substrate solution was as follows: phosphate buffer 0.1 M, pH 7.4, 5 ml.; Krebs-Ringer phosphate solution, 5 ml.; ATP 0.05 M solution, 2 ml.; sodium acetate 1 M solution, 2 ml.; coenzyme A 70–75 per cent (Sigma 5 mg/50 ml.), 1 ml.; sulphanilamide 0.02 M, 0.02 M  $\text{K}_2\text{CO}_3$  in solution, 0.15 ml.

The experimental animals were white female rats of Wistar strain, and male guinea-pigs and dogs. The animals were starved for some 30 h before the experiment. The following tissues and organs were removed from the animals: glandular stomach, duodenum about 15 cm downwards from the pylorus, about 15-cm length of the ileum, and about 3 g fresh weight of liver and kidney was taken for control purposes. From the kidney only cortex was taken. The pieces of tissue were placed in 50-ml. Erlenmeyer flasks which were stoppered with corks through which 2 glass tubes permitted a continuous flow of oxygen, and the flasks were placed in a Warburg apparatus of  $+37^{\circ}\text{C}$ . After 4 h of incubation, 2-ml. samples were taken and 0.5 ml. of 5 per cent trichloroacetic acid solution was added to them in order to stop the reaction and precipitate the proteins.

Table 1. ACETYLATION OF SULPHANILAMIDE BY VARIOUS TISSUES IN THE RAT

	Percentage of sulphanilamide acetylated	Tissue protein mg/ml. of substrate
Control	0.0	—
Liver	22.8	1.47
Stomach	10.0	1.27
Duodenum	26.0	1.50
Ileum	14.9	2.07
Kidney	31.6	1.15
Skeletal muscle	0.0	1.28

Table 2. ACETYLATION OF SULPHANILAMIDE BY VARIOUS TISSUES IN THE GUINEA-PIG

	Percentage of sulphanilamide acetylated	Tissue fresh weight (g)
Control	—	—
Liver	13.6–58.8	2–3
Stomach	9.0–30.8	2
Duodenum	23.7	2
Ileum	19.1–32.0	2
Kidney	10.5–22.2	2
Skeletal muscle	—	2

The experiments sought to establish the acetylation of sulphanilamide in the gastro-intestinal tract in addition to that occurring in the liver and kidney. The method described by Bratton and Marshall<sup>7</sup> was used in the determination of sulphanilamide. The analytical method differed from the original procedure, which was evolved for sulphanilamide determination from blood; here, after diazotizing, the test series were allowed to stand overnight in darkness—before the colorimetric measuring of colour intensity—and this produced a considerable levelling out in the parallel determinations.

To control the protein content of the tissues in the different experimental series, nitrogen determination was performed by the micro-Kjeldahl method. The results (Table 1) showed that acetylation occurs on a relatively large scale also in organs and tissues other than the liver and kidney.

The sulphanilamide concentration used in the experiments corresponds to 34.4  $\mu\text{g/ml}$ .

The results of the experiments with dog were completely negative for all the tissues, as has already been reported earlier for the liver<sup>8–10</sup>. However, the dog has been found to possess an enzyme system for the acetylation of amines other than glucosamine<sup>9</sup>.

In addition, both acetone-dry tissue powders and tissue homogenates were experimented with, but they failed in these experimental conditions to give a positive result in a single animal.

The results show that the gastro-intestinal tract also possesses a fairly distinct capacity for acetylation in addition to its other detoxication reactions.

### Dissociation of Facilitatory Mechanisms in the Midpontile Decerebrate Cat

VAGOTOMIZED, midpontile decerebrate animals have been reported to exhibit decerebrate rigidity, apneustic breathing, tachycardia and arterial hypertension<sup>1,2</sup>. These manifestations of hyperactivity in the somatic postural, respiratory, and cardiovascular systems are abolished by transections of the central neuraxis at or caudal to the level of the pontomedullary junction<sup>1</sup>. These parallelisms suggest the hypothesis that interdependent if not identical facilitatory mechanisms in the lower pons are responsible for these hyperactive states. This hypothesis has been experimentally tested here.

Thirty-six adult cats were anaesthetized with ether and were subjected to midmesencephalic decerebration and vagotomy. The vagi were sectioned at the level of the fifth or sixth cervical vertebra. Afterwards, the brain stem was transected serially until midpontile decerebration was achieved.

The decerebrations were performed by a combination of ischaemic<sup>3,4</sup> and transection procedures. The common carotid arteries and their major branches were ligated. The basilar artery was exposed and then occluded at variable positions along its length by the application of silver clips. In alternating sequence with the placement of the basilar clips, the brain stem was transected at progressively more caudal levels, but always at planes rostral to the most caudal basilar clip. This alternation of basilar artery occlusions and brain stem transections normally minimized the problem of haemorrhage.

The critical level of decerebration in these experiments was the midpontile plane. During the course of an experiment, the physiological manifestations of decerebrate rigidity, apneustic breathing, tachycardia, and arterial hypertension provided very valuable criteria for judging this desired functional level of decerebration. Post-mortem examination of the brain provided anatomical evidence for determining the level and the extent of the surgical transections. Midpontile decerebration was taken to be transection through or immediately above the rostralmost portions of the acoustic tubercles and the trapezoid bodies.

Twenty-six vagotomized, midpontile decerebrate cats were given intravenous injections of urethane. In cats this drug has an effective narcotic action without significantly affecting normal somatic postural, respiratory, or cardiovascular reflex activity<sup>5</sup>. Each injection, 200 mg of urethane, constituted less than 20 per cent of the dosage generally recommended for surgical levels of narcosis. Successive injections were administered at intervals of 15–60 min until the hyperactivities in the three physiological systems under investigation were abolished.

Fig. 1. Kymograph record of respiratory and cardiovascular responses to an intravenous injection of 200 mg of urethane (U) in a vagotomized, midpontile decerebrate cat. Respiration (recorded with a Krogh-type spirometer) changed from apneustic breathing to apnoea. Arterial blood pressure (recorded with a mercury manometer) reflected the changes in respiration but exhibited no significant depression in mean pressure level. Heart beat oscillations in the blood pressure tracing revealed no significant alteration in heart rate.

Significant differential effects on the hyperactive states in the somatic postural, respiratory, and cardiovascular systems were produced by the urethane. The somatic postural system was by far the most susceptible of the three systems to the depressant effects of the narcotic. Decerebrate rigidity consistently was markedly diminished, often abolished, by the initial injection of urethane even when no observable depression of the apneustic breathing or the cardiovascular hyperactivity occurred. The respiratory system was next in the order of susceptibility to urethane depression; the cardiovascular system was the least susceptible. In 17 of the 26 experiments in this series, apneustic breathing was markedly depressed or transiently abolished without significant concomitant depression in the cardiovascular system. In these 17 experiments, apneustic inspirations became shorter and more shallow in 9 animals, gasping respiration appeared in 4 animals, and apnoea occurred in 4 animals (Fig. 1). In the apnoeic group, when respiration reappeared a brief period of gasping respiration sometimes preceded the recurrence of apneustic breathing.

Ten vagotomized, midpontile decerebrate animals were observed throughout spontaneous deterioration to death. Their survival times after vagotomy and midpontile decerebration ranged between 4 and 8 h. The cardiovascular hyperactivity, particularly the arterial hypertension, was consistently the first to fade. Apneustic breathing and decerebrate rigidity tended to undergo progressive deterioration together; however, a moderate degree of spasticity often survived the last traces of apneustic breathing. It is noteworthy that the deterioration of the hyperactive states in this group of animals occurred in a reversed order from that obtained with urethane depression. The depressant effects of the urethane, therefore, cannot be attributed simply to progressive degeneration of the brain stem along its rostro-caudal axis. Rather, the results suggest that the urethane had a differential depressant effect on the brain stem facilitatory mechanisms responsible for the hyperactive states in the three systems.

The results obtained during this work reveal that the described hyperactive states in the somatic postural, respiratory and cardiovascular systems may each be dissociated from the other two. Thus these results do not support the hypothesis that interdependent or identical facilitatory mechanisms are responsible for these hyperactive conditions. On the contrary, the results indicate that decerebrate rigidity, apneustic breathing, and cardiovascular hyperactivity in vagotomized, midpontile decerebrate animals are each supported by a facilitatory

mechanism capable of functioning independently of the facilitatory mechanisms responsible for the hyperactivities in the other two systems. This conclusion does not deny the existence of co-ordinative interrelationships among the facilitatory mechanisms for the three systems, but merely asserts their capacities for independent action.

In view of the prominent position of the bulbar reticular facilitatory system of Magoun<sup>6</sup> in neurophysiological theory, it is pertinent to consider this facilitatory mechanism as it might relate to the phenomena described in this communication. The aggregate results of Bach and Magoun<sup>7</sup>, Bach<sup>8</sup>, and Domino<sup>9</sup> suggest that neither decerebrate rigidity, apnoeustic breathing, nor cardiovascular augmentation in midpontile decerebrate animals is primarily attributable to the bulbar reticular facilitatory system.

This investigation was supported by grant HE 03755 from the National Institutes of Health, U.S. Public Health Service.

## PHARMACOLOGY

### Interaction of the Analgesic Effects of Morphine and Codeine in Rats

In the experiments described here, the analgesic effects of 5.0 mg/kg of subcutaneous morphine and 60.0 mg/kg of subcutaneous codeine were determined individually at various intervals after the injections. Then, a dose of codeine too low to exert any analgesic effect by itself, when given simultaneously with morphine was demonstrated to increase the intensity and persistence of

Fig. 1. Influence of a non-analgesic dose of codeine on morphine analgesia in rats. Drugs were given by subcutaneous injections and the analgesic effects determined by the hot plate method. Reaction times were read immediately before the injections (control readings) and then 30, 60, 90 and 120 min later (abscissa). The ordinate denotes the mean reaction times of rats in each group; vertical lines indicate the standard errors of the means. Morphine (5.0 mg/kg) was given to rats in one group and 3.5 mg/kg of codeine to rats in a second group, while rats in a third group received both drugs simultaneously. Rats in a fourth group received water only.  $N$  = number of animals in each group. Statistical analyses of mean values (' $t$ ' test): \* Statistically different ( $P' < 0.05$ ) from corresponding water controls. # Not statistically different ( $P' > 0.05$ ) from corresponding water control. (a), (a); (b), (b); (c), (c); statistically different ( $P' < 0.05$ ). # Scatter of results statistically different ( $P' < 0.05$ ) from that of corresponding water control (variance ratio test<sup>2</sup>).

Fig. 2. Influence of a non-analgesic dose of morphine on codeine analgesia in rats. Morphine was given in amounts of 0.295 mg/kg and codeine in amounts of 60.0 mg/kg. Analgesia was determined at 30, 60, 90, 120 and 150 min after the injections (for explanations, see Fig. 1). Tests of significance (' $t$ ' test, variance ratio test<sup>2</sup>): \*, # as in Fig. 1. (a), (a); (d), (d); (e), (e); not statistically different ( $P' > 0.05$ ). (b), (b); (c), (c); statistically different ( $P' < 0.05$ ). Mean reaction times of rats given morphine (5.0 mg/kg) and codeine (60.0 mg/kg) were not statistically different at 30 or 60 min ( $P' > 0.05$ ), but at 90 min after the injections ( $P' < 0.05$ ) compare Figs. 1 and 2.

morphine analgesia. A similar experiment was performed with 60 mg/kg of codeine given with a dose of morphine too low to show analgesia.

The analgesic effect was determined by the modified hot plate method<sup>1</sup>. No rat was allowed to stay on the hot plate for longer than 30 sec; therefore, maximal analgesic effect obtainable was 30 sec. Morphine was always injected subcutaneously in the middle of the back

in the midline. When codeine was given alone subcutaneous injections were also made in the middle of the back. When both drugs were given to the animals, codeine was injected subcutaneously in the gluteal region immediately after morphine and from another syringe. Morphine sulphate and codeine phosphate were dissolved in distilled water. Injected volumes were 2 ml/kg and injections were given by means of tuberculin syringes, calibrated to deliver 0.01 ml. Doses refer to the drugs as bases. Male Holtzman rats (180–240 g) were used—each animal only once. The results are summarized in Figs. 1 and 2.

A significant and equianalgesic response was seen at 30 and 60 min after the high doses of morphine (5.0 mg/kg) and codeine (60.0 mg/kg). Mean reaction times of the water controls and the morphine rats did not differ significantly at 90 min. At 120 min the morphine rats were, with one exception, down at the pre-injection level (Fig. 1). The mean reaction time of the codeine rats was still significantly longer at 90 and 120 min than that of the control rats. Although the mean reaction times of the two groups did not differ significantly at 150 min, the significantly different scatter of the two sets of results around their means stressed the persistence of codeine analgesia (Fig. 2).

The low doses of morphine and codeine, being approximately 1/17 part of the higher doses, were, as is already mentioned, without analgesic action. However, when the low dose of codeine was given with the high dose of morphine, the mean reaction times were found significantly longer at 60 and 90 min than after the morphine alone (Fig. 1). A similar but more persistent effect was observed after codeine plus the low dose of morphine. It is of interest that the synergistic action was not significant at 30 min after the injections.

We have no ready explanation for the synergism of morphine and codeine shown here. The drugs were injected subcutaneously, but in different areas. A peripheral mechanism is therefore *a priori* rather unlikely. The greater persistence of codeine analgesia may be due to different rates of absorption of morphine and codeine from subcutaneous tissues<sup>1</sup>.

The reciprocal synergistic actions of morphine and codeine may be a phenomenon peculiar to the rat. Nevertheless, this phenomenon deserves further investigation, for example, in clinical pharmacological investigation in the human being.

## PATHOLOGY

### Modification of Ultra-violet Erythema by Epidermal Stripping

Rottier<sup>1</sup> and Rottier and Mullink<sup>2</sup> reported that removal of the stratum corneum by stripping increases the erythema produced by 297 mμ light and decreases the erythema to 254 mμ. From this observation Rottier postulated that the erythema production mechanism was different at these two wave-lengths. Claesson, Juhlin and Wettermark<sup>3</sup> were unable to confirm these findings and reported increased erythema production at both wave-lengths. In the present investigation the effect of multiple wave-lengths of light on skin with and without stratum corneum was determined.

The ultra-violet light was provided by a xenon-arc monochromatic system described elsewhere<sup>4</sup>.

A 2 cm × 4 cm area on the forearms of ten young adults was stripped from eight to twelve times with 'Sello-tape' to remove stratum corneum. Both the stripped and adjacent unstripped control skin were irradiated with equal quantities of 254 and 297 mμ light. The erythema responses were graded 0-4+ after 8 h.

In five persons, one side of the back was stripped from eight to twelve times with 'Sello-tape'. Both the stripped and contralateral unstripped skin area were irradiated with varying amounts of energy at different wave-lengths of ultra-violet (250, 254, 260, 270, 280, 290, 297, 300 and 310 mμ). The minimal erythema dose (MED) was determined at each wave-length. The MED on the stripped side was then compared with the MED of intact skin.

In nine out of ten cases, forearm skin irradiated with 254 and 297 mμ light regularly developed greater erythema on skin stripped of stratum corneum (Table 1). A decrease in the MED of stripped skin was observed at nine different wave-lengths between 250 and 310 mμ (Table 2).

Table 1. CUTANEOUS ERYTHEMA AT 8 H

Patient	254 mμ		297 mμ	
	Stripped	Unstripped	Stripped	Unstripped
1	+++	+	+++	+
2	++	+	+++	++
3	++	+	+++	+
4	+++	++	+++	++
5	+++	++	+++	+
6	++	+	++	+
7	+++	++	+++	+++
8	++	++	+++	++
9	+++	+++	++	+
10	++	+	+++	+

Table 2. DECREASE IN MINIMAL ERYTHEMA ENERGY PRODUCED BY STRIPPING THE STRATUM CORNEUM

Wave-length (mμ)	Control MED minus stripped MED (Average 5 cases) (mW-sec/cm <sup>2</sup> )
250	3,736
254	3,414
260	3,181
270	3,445
280	1,351
290	3,551
297	6,071
300	4,921
310	18,500

The increase in the erythema resulting from irradiation after removal of the stratum corneum suggests that an important function of this epidermal layer is to protect the underlying tissues from harmful rays. Urocanic acid, a strong absorber of ultra-violet light, has been shown to be a regular constituent of the horn layer<sup>5,6</sup>. This compound may be the principal substance responsible for the observed protection conveyed by stratum corneum. These observations also suggest that the mechanism of erythema production is the same for each of the wave-lengths between 250 and 310 mμ and that the erythema-producing substance is produced or released at levels below the stratum corneum regardless of the wave-length of the eliciting light.

## IMMUNOLOGY

### Reciprocal Relationship of Antigens 'I' and 'i' in Health and Disease

Giblett and Crookston<sup>1</sup> have recently described in thalassaemia and certain other diseases an increase in strength of the 'i' antigen in the red cells of adults without an apparent reciprocal decrease in 'I' antigen strength. McGinniss *et al.*<sup>2</sup> reported a decrease in 'I' antigen strength in the red cells of adults in leukaemia, but had not tested with anti-'i'. We have examined a case of leukaemia with weakened 'A' antigen in which the 'I' antigen was also depressed. Here, the 'i' antigen was stronger than in average adult cells so that the 'Ii' reciprocal relationship was maintained.

In the cases described by Giblett and Crookston, the estimation of the strength of the 'I' and 'i' antigens appears to be based entirely on agglutination titres. We suggest that a state of excessive erythrocyte sensibility to agglutination by anti-'I' and anti-'i' may exist in certain disease states, so that titration scores alone may not reflect the true antigen strength. Absorption and elution experiments would be useful in demonstrating the ability of the red cells to take up more than average amounts of the antibodies.

We have observed in an apparently healthy donor that both 'I' and 'i' were at the upper end of the normal distribution curve, which suggested the presence of a higher amount than normal of the precursor substance of 'i' prior to the development of 'i' in the red cells of this person.

It appears that in a few healthy adults and in certain disease states the usual 'Ii' reciprocal antigen strength is disturbed. Whether this is due to a genetically determined abundance of 'i' substance from which only a normal amount is utilized for conversion to 'I', or whether the 'i' antigen strength is stimulated by virtue of the disease is conjectural at present. We seek evidence of a change in the 'Ii' antigen strength during the development of a disease process. Such a change in 'Ii' status would support Giblett and Crookston's theory of "proliferative stress on early erythroid precursors".

### Induction of an Immunological Response in Local Lymph Nodes by Chemical Carcinogens

AFTER a period during which intensive investigation of carcinogenesis continued along classical lines, there has recently developed a major shift in emphasis as it is becoming more apparent that certain carcinogens, even when applied locally, are capable of initiating significant changes in the genetic apparatus of the host cells. Some of the present developments have, to a large extent, been the outgrowth of investigations showing that some carcinogens arrest the synthesis of DNA dependent RNA, in a manner similar to actinomycin-D. Structurally related non-carcinogens, on the other hand, exert no such action. These results indicate the possibility that the initial event in carcinogenesis might be an impairment in the expression of genetic (DNA dependent RNA) information, as has been suggested recently by De Maeyer and

De Maeyer-Guignard<sup>1</sup>. Gelboin and Klein<sup>2</sup> have, moreover, shown that tumour formation by 7,12-dimethylbenz(a)anthracene can be markedly inhibited by the topical application of actinomycin-D before and after treatment. This would also support classical models for carcinogenesis such as that suggested by the work of Monod and Jacob on genetic systems in micro-organisms<sup>3</sup>.

In the course of immunological investigations on contact sensitivity with dinitrofluorobenzene (DNFB) and oxazolone (2-phenyl-4-ethoxymethylene oxazolone) in the guinea-pig<sup>4,5</sup> it was found that topical application of these agents was followed by the appearance of large pyroninophilic cells (LPC) in draining lymph nodes four days later, one day before the animal developed contact sensitivity; this reaction was immunologically specific<sup>4</sup>. Taken together with recent trends in cancer research and virology this has led us to consider the possibility that some carcinogens could be acting in a manner akin to compounds such as DNFB. If the stimulation of carcinogenesis by DMBA paralleled that of local lymph nodes by the cutaneous application of DNFB and oxazolone, one could expect that in mice sensitive to carcinogenesis the cutaneous application of a chemical carcinogen would provoke the appearance of LPC in local nodes; in contrast structurally similar non-carcinogenic components would be found relatively inactive.

Experiments were performed with several strains of mice and guinea-pigs with 3,4-benzpyrene (BP) and 7,12-dimethyl-1,2-benzanthracene (DMBA) as carcinogens, and anthracene as a structurally related non-carcinogen. It was found that LPC were indeed elicited by BP and DMBA at the appropriate time and to a higher degree in mice sensitive to carcinogenesis, whereas in the draining lymph nodes of control mice painted with the anthracene much smaller numbers of LPC were observed, in a range comparable with untreated mice. These results were compared with the reaction of lymph nodes of mice to the cutaneous application of oxazolone and DNFB.

Five strains of mice were examined: (1) Random bred albino mice (Tuck) obtained from Messrs. A. Tuck, Rayleigh, Essex. (2) Rudiger strain (*Ru*). This strain was obtained from Dr. K. H. Schmidt-Ruppin, Geigy A.-G., Basle, and has a heightened susceptibility to tumour transplants and cancer induction<sup>6,7</sup>. (3) *C57BL* from the Medical Research Council Rheumatism Research Unit, Taplow, Bucks. (4) *C<sub>3</sub>H*. (5) *DBA/2* from a stock held at the Forschungsinstitut, Davos. The guinea-pigs used were of the Hartley strain. The BP and DMBA were obtained from Fluka A.-G., Buchs, Switzerland, as also was the anthracene used as a control. DNFB was obtained from British Drug Houses, Ltd., and oxazolone was prepared according to Cornforth<sup>8</sup>. The carcinogens and DNFB were dissolved as a 5 per cent solution in an equal volume of acetone and olive oil; in some experiments the olive oil was replaced by croton oil. The oxazolone was dissolved as a 10 per cent solution in ethanol, and anthracene as a 5 per cent solution in equal volumes of olive oil and hot benzene. These solutions were painted on the left ears of both guinea-pigs and mice on one occasion only. The draining auricular lymph nodes were removed 4, 5, 9 and 10 days after application of the chemical agent to the ear, fixed in Carnoy's solution, and prepared for histological examination by conventional means. Sections were cut at 5 $\mu$  and stained with methyl-green pyronin.

The number of large pyroninophilic cells were counted in four adjacent microscopic fields of diameter 125 $\mu$  in the area previously defined as the paracortical area of the cortex<sup>9</sup>, where these cells were present at greatest concentration. Care was taken not to include those cells forming obvious germinal centres.

The significant increase in the number of large pyroninophilic cells present in the draining lymph nodes of mice and guinea-pigs on the fourth and fifth days after the application of a chemical carcinogen is shown by the data in Table 1; these findings contrasted with the

number of LPC present in normal nodes or in nodes on the fourth and fifth days after the application of anthracene or solvent alone. In Tuck albino mice and *C57BL* mice the number of cells found in local lymph nodes on the fourth day after the application of DNFB and oxazolone was somewhat higher than that following the application of BP or DMBA. The presence of croton oil did not increase the number of large pyroninophilic cells present in the cortex of *Ru* mice treated with DMBA; however, croton oil alone evoked a relatively high concentration of these cells.

Table 1. MEAN VALUE OF NUMBER OF LARGE PYRONINOPHILIC CELLS FOUND IN FOUR ADJACENT MICROSCOPIC FIELDS, EACH OF DIAMETER 125 $\mu$ , IN THE DRAINING LYMPH NODE

Treatment	(a) 4-5 days after application of carcinogen or solvent					
	Tuck	<i>Ru</i>	Mice <i>C57BL</i>	<i>C<sub>3</sub>H</i>	<i>DBA/2</i>	Guinea-pigs
Anthracene (in olive oil-benzene)	35 (6)	29 (6)	13 (6)	11 (4)	19 (6)	4 (4)
Benzene		38 (4)				
BP (acetone-olive oil)	62 (6)		76 (6)	44 (6)	46 (6)	96 (4)
Olive oil		33 (4)				
Acetone		33 (4)				
DMBA (acetone-olive oil)	99 (6)	96 (6)	77 (6)	49 (7)	46 (7)	93 (4)
DMBA-croton oil		93 (6)				
Croton oil		120 (4)				
Treatment	(b) 4 days after application of chemical sensitizing agent					
	Tuck	<i>C57BL</i>				
Unpainted (control)	33 (6)	20 (7)				
DNFB	162 (4)	96 (4)				
Oxazolone	159 (4)	95 (4)				

Figures in brackets indicate number of animals examined. All counts were of cells lying within the 'paracortical area' of the cortex of the lymph node. No cells within germinal centres were included. The areas examined were selected as those in which large pyroninophilic cells were present at highest concentration.

Lymph nodes were also examined 9 and 10 days after application of carcinogens or sensitizing agents. In all cases the proportion of large pyroninophilic cells had dropped to the level found in normal auricular lymph nodes. No increase in germinal centre development or plasma cell formation was found at any stage in the auricular nodes of mice. However, it should be noted that unstimulated auricular nodes of mice were far more active than those of guinea-pigs. This is probably due to a wider area of lymphatic drainage and this would also account for a high normal background of large pyroninophilic cells in the auricular lymph nodes of mice as compared with those from guinea-pigs.

Random bred albino mice have been shown to be more susceptible to skin carcinogenesis than *C57BL* mice and these in turn to be more susceptible than *DBA* mice<sup>9,10</sup>. Consequently, our findings would be consistent with a direct correlation between susceptibility to skin carcinogenesis in the mouse and the cellular changes in the local lymph node associated with the development of contact sensitivity. Indeed, *Ru* mice, a strain showing the highest susceptibility, was also one of the lines showing the strongest lymph node reactivity. It is of interest that the presence of croton oil, which also evoked the development of large pyroninophilic cells and has a marked enhancing effect on skin carcinogenesis<sup>11</sup>, did not alter the reactivity of the local lymph node to DMBA when croton oil was used as the solvent instead of olive oil.

Our results should be evaluated in relation to the work of Old *et al.*<sup>12</sup>, who investigated contact sensitivity to carcinogenic polycyclic hydrocarbons in the guinea-pig. They considered that the high degree of delayed sensitivity evoked by these carcinogens in this species might be of importance in understanding the relative resistance of guinea-pigs to chemical carcinogenesis. On the other hand, in mice, highly susceptible to chemical carcinogenesis, they were unable to induce the evidence of delayed sensitivity, so readily elicited in guinea-pigs. Mice have been reported by Crowle and Hu<sup>13</sup> to develop contact sensitivity to dinitrochlorobenzene, and similar observations have been made by G. L. Asherson (unpublished observation), though these reactions may often be

difficult to demonstrate. Moreover, mice show a normal rejection of homografts, a reaction generally believed to involve delayed-type hypersensitivity. It would therefore appear that poor contact sensitivity in mice is due to a failure of reaction in the periphery rather than a failure of the central immunological mechanisms which appear to be as well developed in the mouse as in the guinea-pig.

The large pyroninophilic cells in lymph nodes during the development of contact sensitivity have been shown to be in a premitotic state<sup>4,5</sup>, as have cells with a pyroninophilic cytoplasm in tissue cultures and cultures of leucocytes stimulated by antigens. To what extent these states are related is not known, but investigations of agents which are known to affect specific cell pathways, particularly of the genetic apparatus, might be rewarding.

In summary, this work suggests that some carcinogens can act as sensitizing agents in mice, evoking LPC in local lymph nodes. The ability of certain strains of mice to show changes in their lymph nodes associated with the development of contact sensitivity closely parallels their susceptibility to skin carcinogenesis.

We thank Mr. C. J. Heather for preparing the histological material, and Miss Tienke van't Hof for her help.

## RADIOBIOLOGY

### Pyromellitic, Benzenepentacarboxylic and Mellitic Acids as Radioprotectors

THE radioprotective action of pyromellitic acid in mice was reported by Barnes and Philpot<sup>1</sup>. The work recorded here includes the related acids of higher basicity, which were synthesized as follows:

**Benzenepentacarboxylic acid.** The route described by Fleischer and Retze<sup>2</sup>, starting from tetralin, was followed, with technical modifications. Purification of the product of the penultimate stage by recrystallization was unnecessary; the crude, substituted naphthindanedione, isolated by ether extraction, was distilled through a Vigreux column and collected within the range 211°–216° at 13 mm pressure (lit. b.p. 205°–210° at 12 mm) (found: C, 79.9, 80.1; H, 8.69, 8.58; calc. for C<sub>18</sub>H<sub>8</sub>O<sub>2</sub>: C, 80.2; H, 8.51 per cent). The gum solidified on standing, m.p. 37°–39°. Portions (2 g) were oxidized with fuming nitric acid (s.g. 1.5, 5 ml.) with added water (2 ml.) in 'Pyrex' tubes 60 cm long and about 22 mm in diameter, sealed by drawing out to a capillary. These were heated for 21 h in a thermostatically-controlled Carius furnace, first at

180°, then at 200° for the final 3 h. After allowing to cool, the high pressure was released by heating the capillary near the tip with a looped resistance wire. The clear liquid yielded crude benzenepentacarboxylic acid on chilling. A single recrystallization from concentrated nitric acid (s.g. 1.42) afforded pure acid, m.p. 235° decomposition (lit. m.p. 233° decomposition), after drying *in vacuo* over sodium hydroxide and phosphoric oxide (found: C, 44.2, 44.3; H, 2.17, 1.98; calc. for C<sub>11</sub>H<sub>6</sub>O<sub>10</sub>: C, 44.3; H, 2.03 per cent). Further pure material was obtainable by evaporation of mother-liquors and recrystallization. 16 g naphthindanedione gave a total of 10.2 g pure acid (61 per cent). The acid was readily soluble in water.

**Mellitic acid.** Permanganate oxidation of hexamethylbenzene, as described by Fishwick<sup>3</sup>, proved unsatisfactory owing to steam-volatilization of the starting-material. Oxidation of hexa(hydroxymethyl)benzene (Chaigneau<sup>4</sup>) failed to give a pure product. Heating hexamethylbenzene with fuming nitric acid in a sealed tube under the conditions given by Wibaut *et al.*<sup>5</sup> gave an incompletely oxidized product, m.p. 290° decomposition, with previous sintering, after precipitation from dioxan with benzene (found: C, 43.4, 43.6; H, 2.35, 2.66; calc. for C<sub>6</sub>(COOH)<sub>6</sub>: C, 42.1; H, 1.77. CH<sub>3</sub>C<sub>6</sub>(COOH)<sub>6</sub> requires: C, 46.15; H, 2.58 per cent). 0.171 g neutralized 27.5 ml. 0.1 N NaOH (theor.: 30 ml.) using methyl red as indicator. The infra-red absorption spectrum of this material (product A) was identical with that of an authentic specimen of mellitic acid. More vigorous oxidation conditions were used: hexamethylbenzene (2 g) fuming nitric acid (s.g. 1.5, 7 ml.) and water (2 ml.) were heated in a sealed tube (see above) at 120° for 3 h. The tube was allowed to cool, opened and further fuming nitric acid (3 ml.) added, then resealed and heated at 180° for 16 h. The contents of four tubes, a clear, green solution, on evaporation *in vacuo* gave 5.67 g crude mellitic acid. Recrystallization from nitric acid (65 per cent, 160 ml.) keeping overnight at 4°, gave pure acid (4.32 g, 26 per cent) m.p. 295°–300° decomposition, after drying *in vacuo* (found: C, 42.1, 41.9; H, 1.82, 1.94; calc. for C<sub>12</sub>H<sub>6</sub>O<sub>12</sub>: C, 42.1; H, 1.77 per cent). This neutralized the theoretical amount of NaOH.

The pattern of radioprotection and acute toxicity experiments, the conditions and the mice used were as previously described<sup>1,6</sup>. In all cases, acids were injected intraperitoneally as neutral, aqueous solutions of the sodium salts. Injections were given 10 min before irradiation.

Mellitic acid protected neither at its LD<sub>50</sub> (~0.5 m moles/kg) nor at lower doses, but the incompletely oxidized product A (see above), containing material of lower basicity, was less toxic and protected considerably (Table 1). As expected, benzenepentacarboxylic acid (BPCA) had favourable properties. The LD<sub>50</sub> is about 8 m moles/kg and no deaths were observed in mice given 5 m moles/kg or less. Highly significant survival (*P* < 0.01) was shown in groups of mice given 4 or 5 m moles/kg before a normally lethal dose (1,025 r.) of X-rays (Table 1). BPCA raised the LD<sub>50</sub> of X-rays for mice of *R* stock, normally 897 (± 6) r., to 1,106 (± 28) r.; it was therefore significantly less protective than AET, which gave a value of 1,337 (± 69) r. (Table 2).

Radioprotective doses of BPCA caused slight depression as in the case of pyromellitic acid, but with some evidence of hypocalcaemic tetany which increased with increasing dosage. The toxic effects were antagonized by calcium; while 5 mice given 10 m moles/kg BPCA died within a few minutes showing marked tetany, 5 given the stable solution containing the same dose in admixture with an equimolecular amount of calcium chloride were unaffected. The difference in survival is highly significant (*P* < 0.01). It may be noted that a dose of 10 mmoles/kg calcium chloride is not tolerated when given alone; the LD<sub>50</sub> is about 3 mmoles/kg. Such an interaction between the toxic effects of calcium and a radioprotector was demon-

Table 1. PROTECTION AGAINST 1,025 r. X-RAYS

Compound	Dose/kg body wt.	No. survivors out of 10 mice at 30 days

\* Reduction in survival significant ( $P < 0.05$ ).

strated for tetrametaphosphate and EDTA<sup>6</sup>, but it was not evident in the case of cysteamine. Radioprotection by BPCA was virtually abolished by adding calcium (Table 3). It is clear that for BPCA, as shown<sup>6</sup> for inorganic condensed phosphates and EDTA, both toxic effects and radioprotection in the mouse are due to a lowering of calcium-levels. Tetany is unlikely to be involved in protection by BPCA since its prevention<sup>6</sup> by mephenesin did not significantly affect protection: survival after 1,025 r. in mice given BPCA alone was 28/40 and 19/36 in mice given BPCA and mephenesin. Therefore, like certain condensed phosphates<sup>6</sup> BPCA probably protects through circulatory depression with consequent hypoxia.

In the case of pyromellitic acid, evidence on the mode of protection was less readily available. The possibility of an effect on calcium could not be tested directly because the calcium salt is insoluble; injection of mixtures would not have been informative. Conceivably, pyromellitic acid might affect calcium levels by precipitation. Tetany was not observed but might have been masked by an accompanying depressive action. In a self-contained experiment, confirming a previous result<sup>1</sup>, a dose of 9 mmoles/kg was significantly more protective ( $P < 0.05$ ) than one of 12 mmoles/kg (Table 4). It should be noted that, of mice given 12 mmoles/kg, none died within 5 days of irradiation, that is, the lower survival in this group was not accounted for by an additive toxic effect of radiation and the drug but by a higher radiosensitivity. The occurrence of this phenomenon, of an optimum dose below the maximum tolerated, suggests that for pyromellitic acid the mechanism of protection differs from that of toxicity. It also suggests that pyromellitic acid protects differently from agents not showing the phenomenon: among these are polyphosphates<sup>6</sup> and BPCA (Table 4), the protective and toxic effects of which are due to calcium depletion.

Both protection by and toxicity of pyromellitic acid, at a given dose, depended on the molarity of the solution injected. Thus a dose of 9 mmoles/kg was significantly<sup>1</sup> more protective ( $P < 0.05$ ) at 0.30 M than at 0.15 M (Table 4). A dose of 16.5 mmoles/kg at the higher concentration killed 9 mice out of 10, but at the lower, only 3; the difference is significant ( $P < 0.05$ ). An explanation might be that material injected at the higher concentration would more rapidly reach an effective level in the blood. Protection by pyro- or tripolyphosphate was unaffected by concentration<sup>6</sup>: the difference might be explained by assuming a greater ability of the smaller inorganic molecules to pass into the blood. However, protection by 4 mmoles/kg BPCA was reduced by increasing the concentration, while that by 5 mmoles/kg was unaffected (Table 4).

In view of the foregoing evidence, it seems unlikely that pyromellitic acid protects through an effect on calcium. The fact that the radioprotective dose is very high suggests the possibility of a physical process. Conceivably, the osmotic effect of a high concentration of a polyionic substance, of low diffusibility, in the peritoneal cavity could lead to a hypoxic condition as a result of haemoconcentration. The effect of concentration on protection lends support to this idea. It could be suggested that such a process may contribute to the effects of a number of radioprotectors which are effective only in high dosage.

Since the product of incomplete side-chain oxidation of hexamethylbenzene, product A, showed considerable radioprotective effect it is suggested that benzene tetra- or penta-carboxylic acids with inert groupings, for example, alkyl or halogen, in the unsubstituted ring positions would repay investigation as radioprotective agents. These compounds, however, present considerable problems in organic synthesis.

I thank Mrs. D. M. R. Lowman and Mr. V. Saxton for their help, Mr. M. J. Corp for arranging irradiations and Mr. J. St. L. Philpot for discussions.

## BIOLOGY

## Induction of Tension Wood by 2,3,5-Triiodobenzoic Acid

TENSION wood, the reaction wood of angiosperms, is usually formed as a morphogenetic response to geotropic and other orientation movements of stems and branches. In general it is formed on the upper side of leaning stems and its formation is thought to be a regulatory response, maintaining the stems and branches in specific orientations. Anatomically, tension wood is characterized by fibres with a conspicuously thickened inner layer of the cell wall, the gelatinous layer, which is unligified or only partially lignified. In addition there is a marked reduction in the size and number of vessels in comparison with adjacent normal wood<sup>1</sup>. An eccentricity of growth is frequently associated with tension wood formation, with wider growth rings evident on the tension wood side<sup>2</sup>.

The formation of tension wood is one of the few responses of plants to stimuli involving physiological processes which result in recognizable changes in anatomy.

Fig. 1. *Acer rubrum*. Photomicrograph of a transverse section showing a ring of tension wood fibres (arrows) in a stem treated with 2,3,5-tri-iodobenzoic acid. Safranin light-green stained. ( $\times 75$ )

Our observations indicate a similar anatomical response following the application of the auxin-antagonist 2,3,5-tri-iodobenzoic acid (TIBA). That TIBA may have profound effects on wall differentiation was indicated some years ago by Gorter<sup>3</sup>, who observed that the germination of *Lepidium sativum* on porous plates soaked with a 0.02 per cent solution of TIBA is accompanied by the abnormal deposition of a mass of cell wall material at the tip of root hairs. Following the lateral application of TIBA to internodes of seedlings we have been able to induce the formation of tension wood similar in anatomy to natural tension wood. TIBA is a well-known auxin-antagonist the precise mode of action of which is still unknown; however, in general it is thought that its action is effected through an interference with the normal auxin system of the plant. As auxin has been shown to be involved in most stages of normal plant cell differentiation we have used TIBA with the expectation that changes in the differentiation of cambial initials could be induced. TIBA was applied in various concentrations of 0.25–2.0 per cent as a dispersion in lanolin. The lanolin paste was applied laterally as a ring around internodes of actively growing *Acer rubrum* seedlings.

A few days after the application the stem swelled above the TIBA rings and, at various times following the application, sections were cut from the regions above and below the ring. Fig. 1 is a cross-section of an 8-week-old seedling cut about 1/3 in. below a ring of 1.0 per cent TIBA in lanolin paste which had been applied 27 days previously. A band of fibres around the stem may be observed, which have a conspicuous thick inner layer of cell wall material. This inner layer stains green following normal safranin light green staining<sup>4</sup>. Very few vessels are evident in this ring. A transverse section of a similar specimen, showing part of the tension wood band and photographed with bright field, polarizing and fluorescent microscopes appears in Figs. 2, 3 and 4.

With bright field illumination (Fig. 2) the thickened inner layer of the secondary wall of the tension wood fibres is evident. It comprises the bulk of the secondary wall. Between crossed Nicols this inner layer is dark and only the outer region of the secondary wall appears bright, indicating that the thick inner layer is similar in organization to the 'gelatinous' layer of natural tension wood. In the fluorescence microscope, with ultra-violet illumination, the distribution of lignin can be observed in

the cell walls (Fig. 4). Lignin is absent from the thick inner layer and is concentrated in the outer region of the cell wall; again this is characteristic of tension wood fibres. The distribution of peroxidase has been determined in adjacent sections by the McJunkin method<sup>5</sup> using benzidine and peroxide. In the tension wood induced by TIBA intense peroxidase activity was observed in the unligified region of the fibre cell walls. Peroxidase activity was also evident in both pith and cambial regions.

The anatomy of the stem above the point of application of TIBA is also modified. Sometimes tension wood fibres occur in this region, but the main anatomical change we

Fig. 2. *Acer rubrum*. Bright-field micrograph of an unstained transverse section of a similar specimen to that shown in Fig. 1 showing details of the tension wood. The fibres have a conspicuous thick inner layer. ( $\times 600$ )

Fig. 3. *Acer rubrum*. The same specimen as in Fig. 2 between crossed Nicols. The thick inner layer is of low birefringence. ( $\times 600$ )

Fig. 4. *Acer rubrum*. The same specimen as in Figs. 2 and 3 photographed using a fluorescence microscope. The outer part of the cell wall shows intrinsic fluorescence, indicating that lignin is concentrated in that region. ( $\times 600$ )

observed was the formation of groups of vessels with a characteristic angular appearance.

These observations on *Acer rubrum* are of interest in that they give some insight into the causation of tension wood at the hormonal level. The participation of auxins in the development of tension wood has been postulated by Jaccard<sup>6</sup>, Onaka<sup>1</sup> and Nečesný<sup>7</sup>. Wardrop<sup>8</sup>, however, in a discussion of tension wood formation has suggested that auxin is only related to the peripheral distribution of cell division in the cambium. Thimann<sup>2</sup> has deduced that tension wood would be formed in a region where there is an indolyl-3-acetic acid (IAA) deficiency. He argues that tension wood forms on the upper side of stems, the side from which auxin tends to move. The auxin level would be further decreased by the presence of active peroxidase, known to be present in tension wood. Nečesný<sup>9</sup> has shown that when IAA is added to the upper side of stems which are actively forming tension wood, the formation of this tissue was retarded.

Our observations support the view that tension wood is formed under conditions of IAA deficiency. Tension wood is formed below the rings of TIBA, and it has been shown<sup>10</sup> that in petioles of sweet potato TIBA effectively blocks auxin transport, therefore a low auxin concentration is to be expected below the rings of TIBA. We have also observed in preliminary investigations that the induction of tension wood formation by TIBA can be prevented by IAA application.

### Gelatinous Fibres in Ash (*Fraxinus excelsior* L.)

TENSION wood in dicotyledonous trees and shrubs is recognized by the presence of gelatinous fibres. These fibres have an inner layer, composed almost entirely of cellulose (the *G*-layer), which may replace either the *S*<sub>2</sub> or both the *S*<sub>2</sub> and *S*<sub>3</sub> layers of the secondary wall of the fibres. In some instances the *G*-layer may occur in addition to the *S*<sub>2</sub> and *S*<sub>3</sub> layers of the fibre wall. In transverse sections the *G*-layer may commonly be seen to have pulled away from the remainder of the wall on one side.

The difficulty of recognizing gelatinous fibres in ash suspected of containing tension wood has been remarked on by a number of authors<sup>1-4</sup>. The difficulty appears to be due to the lack of a distinct *G*-layer.

Recently a piece of fast-grown ash came into our possession. Sections which were taken from this specimen in order to investigate its lignification showed gelatinous fibres with well-developed *G*-layers. The log had been cut at approximately 3 m above the ground from the main stem of a tree growing in Pinner (Middlesex). There were 13 growth rings (Fig. 1), the widest being the ninth (1 cm). The log was approximately 17 cm in diameter.

Application of phloroglucinol and concentrated hydrochloric acid to the smoothed end-surface of the log showed the early wood of each growth ring to be well lignified, but the extensive late wood was poorly lignified. When transverse sections 20μ thick were treated with these

Fig. 1. Surface view of the log of fast grown ash used in this study ( $\times 0.5$ )

Fig. 2. Transverse section of ash stained with safranin and light green and showing gelatinous fibres in the early wood ( $\times 160$ )

Fig. 3. Gelatinous fibres in the early wood of ash ( $\times 560$ )

reagents the comparatively high degree of lignification in the early wood was seen to be confined to the vessels and parenchyma in that region. The fibres throughout the growth rings were uniformly poorly lignified except for the middle lamella which was well lignified.

Fibres with apparently typical, convoluted, gelatinous layers were widely distributed in the early wood (Figs. 2 and 3). These fibres were almost completely unlignified, with the inner (*G*) layer showing no coloration when tested with phloroglucinol and hydrochloric acid.

When sections were treated with chlor-zinc-iodine the secondary walls of the fibres in the early wood showed a consistent pale violet coloration; this colour was more deeply developed in the convoluted inner layer when this was present. Treatment of the sections with ruthenium red also revealed a distinct inner zone to the secondary wall of the fibres, although no such layer was seen in sections of ash that had been grown at a slower rate.

By the use of differential staining with safranin and light green the gelatinous layer was stained green, with an intensity depending on the degree of lignification. Using chlorazol black *E* and lignin pink<sup>5</sup> the gelatinous layer was stained grey/black with the remainder of the secondary wall pink.

Transverse sections viewed between crossed 'Polaroids' showed the inner convoluted layer of the fibres to be non-birefringent.

The presence of such well-developed gelatinous fibres in ash is of interest, and may well be accounted for by the extremely rapid rate of growth of this particular tree. It is known that the rate of growth affects the formation of reaction wood in conifers<sup>6</sup> and the same may well be true of dicotyledons, although there is no published evidence on this point.

# Senescence of Daffodil (*Narcissus pseudonarcissus*) Cut Flowers treated with Benzyladenine and Auxin

ONE of the kinins, benzyladenine (BA), has been reported to retard the senescence of cut flowers of carnations<sup>1</sup> and King Alfred daffodils after the daffodils have been stored for two weeks at 0.5° C (ref. 2). Later it was found that BA was ineffective on freshly-cut daffodils. In the experiment described below, BA was combined with various concentrations of the sodium salt of 2,4-dichlorophenoxyacetic acid (2,4-D). Both 2,4-D and BA have been reported to be effective in delaying the senescence of cauliflower<sup>3</sup>.

Flowers of field-grown King Alfred daffodils were cut April 3, 1964, and floral parts only were dipped for 5 sec in combinations of 0 and  $5 \times 10^{-4}$  M BA and 0,  $10^{-5}$ ,  $10^{-4}$  and  $10^{-3}$  M 2,4-D. Each solution contained 0.1 per cent 'Tween 20' (sorbitan polyoxyethylene monolaurate). Each treatment was repeated four times and each repeat consisted of three flowers. The stems of these flowers were placed in tap water at a room temperature of 22° C. The replicates were arranged according to a completely randomized design<sup>4</sup>.

Fresh weights of the perianth segments were determined 5 and 6 days after treatment because a loss of fresh weight had previously been found to accompany senescence of cut King Alfred daffodil flowers. Dry weights were made 6 days after treatment to determine the relative importance of water loss. Differences between means were tested by Duncan's multiple range test<sup>5</sup>.

Freshly cut King Alfred daffodils may be preserved by a combination of  $5 \times 10^{-4}$  M BA and  $10^{-4}$  M 2,4-D, but not by BA or 2,4-D alone (Table 1). The preserved flowers were obviously alive and turgid. Flowers treated with  $10^{-3}$  M 2,4-D had badly twisted perianth segments, but flowers dipped in  $10^{-4}$  M 2,4-D did not begin to twist until 6 days after treatment. At this time, their commercial life was terminated despite the fact that they were turgid, with few markings. The successful BA-2,4-D treatments affected the dry weights of the perianth segments very little compared with their marked effect on fresh weights (Table 1). Senescence in daffodils is probably due, at least in part, to a dehydration of the flower. Flowers treated with  $5 \times 10^{-4}$  M BA and  $10^{-4}$  M or  $10^{-3}$  M 2,4-D contained more water than did the checks (Table 1). Water content was determined by subtracting dry weights from corresponding fresh weights.

Kaufman and Ringel found that treatment of cauliflower with 2,4-D retarded abscission and treatment with BA retarded yellowing<sup>6</sup>. The experiment reported here does not indicate whether each chemical has a separate function or not. There is definite indication that both BA and 2,4-D must be present to prevent a dehydra-

tion and ageing of perianth segments of freshly cut daffodils.

Previously, I found that BA preserved daffodil flowers if it was applied after the flowers had been stored at 0.5° C for two weeks<sup>2</sup>. BA alone is ineffective on freshly cut daffodils. The condition of the flower when treated may determine the effectiveness of hormones applied as senescence retardants.

The commercial use of BA and 2,4-D must depend on the cost of BA, as yet available only for experimental purposes, and on the ease of application. A flower dip is not as commercially applicable as a stem dip. However, the movement of BA through plant tissues is primarily basipetally polar<sup>6</sup>, and so cannot be used as a stem dip.

I thank Mr. G. A. Vantreight, Victoria, B.C., for the daffodils, and I also thank the Shell Oil Company of Canada, Ltd., for the benzyladenine used in this experiment. This work was supported by a research grant from the Faculty Research Fund of the University of Victoria.

## Effects of Nutritional Treatments of Seed-bearing Plants on the Performance of their Progeny

HARRINGTON<sup>1</sup> collected seed from carrot, lettuce and pepper plants showing severe deficiencies of several major nutrients and found that the deficiencies had little effect on the percentage germination of the seed. Szukalski<sup>2</sup> applied different amounts of a phosphorus fertilizer to flax and rape plants and showed that when seed from these plants was sown in phosphorus-deficient soil, high levels of phosphorus in the seed were advantageous for seedling growth. Results from Durrant's<sup>3</sup> experiments with flax indicated that nutritional treatments given to flax plants brought about apparently heritable changes. In the present experiments nutritional treatments were applied to watercress, pea and carrot plants and plants from their seed were raised to determine the effects of the seed-plant treatments on the progenies. This communication gives a report of the results obtained.

In experiments with watercress (*Rorippa nasturtium aquaticum* L., Hayek) seed was harvested from plants grown in sand cultures supplied with Hewitt's<sup>4</sup> nutrient solution modified to contain either 0.2, 1.0 or 4.0 m.equiv./l. phosphorus (as ortho-phosphate). Iron was supplied chelated with ethylenediamine tetraacetic acid. Seed from plants grown under the three culture treatments (called  $P_1$ ,  $P_2$  and  $P_3$  seed) had, respectively, 0.47, 0.84 and 0.95 per cent of their dry weight as phosphorus, while differences in their contents of nitrogen and potassium were slight. These seeds were all similar in size and, two months after harvest, all had a germination of more than 90 per cent. The three kinds of seed were then sown in cultures supplied with each of the three solutions, and plant weights were determined after 7-9 weeks of growth. In cultures with the lowest level of phosphorus, plants from  $P_1$ ,  $P_2$  and  $P_3$  seed had a mean dry weight of 0.095 g, 0.139 g and 0.181 g, respectively (*L.S.D.* 0.0252). At the higher levels of phosphorus supply, plant weights did not reflect differences in the phosphorus content of the seed. In further experiments it was found that none of the effects produced by treatments applied to a first

generation of plants had measurably different effects on mean plant weight in the third generation, irrespective of the concentrations of phosphorus in which the second or third generation of plants were grown.

In a glasshouse experiment with a pure line of the pea variety 'Meteor', plants were grown in vermiculite cultures supplied with Hewitt's<sup>4</sup> nutrient solution modified to contain either 0.4 or 4.0 m.equiv./l. of ortho-phosphate in combination with either 1.0 or 10.0 m.equiv./l. of nitrogen as nitrate. Plants given low phosphorus or low nitrogen produced many fewer but only slightly smaller seeds than those given the high N, high P solutions.

The differences in nitrogen nutrition did not lead to different N contents of the seed but seed from phosphorus-deficient plants contained 0.24 per cent P while that from high P plants contained 0.58 per cent P. Seeds from plants which had received the four kinds of nutrient solution were then sown in vermiculite supplied with each of these solutions, giving sixteen treatments. It was found that differences in the nitrogen nutrition of the parent plants had no effect on the weights of the plants produced by their seeds. Plants produced from seeds with a high phosphorus content, however, were significantly larger than those from low phosphorus seeds when the seeds were grown in a low phosphorus medium (Table 1(a)). When plants from the 16 kinds of seed from this experiment were grown in each of the four nutrient solutions, none of the treatments given to the first generation produced measurable differences in plant weights in this, the third, generation.

Peas from a glasshouse experiment where the seed-plants had been grown in the four nutrient solutions described here were also sown in the field in soil of high fertility. The plants were harvested when most of the pods contained fully swollen peas. The mean fresh weights of the plants and of the peas and pods, given in Table 1(b), showed that the seed which was low in phosphorus gave plants that were smaller and had a lower weight of pods than those from the seed not deficient in phosphorus. Nitrogen deficiency in the parent plants had no effect on seed performance.

Further evidence of the effects of differences in seed phosphorus reserves was obtained from an experiment with carrots, using seed produced from plants grown on sixteen field plots receiving different manurial treatments (all combinations of nil and high rate application of mineral nitrogenous, phosphatic and potassic fertilizers and farmyard manure). The manurial treatments had no effect on the size or percentage germination of the seed. It was found, however, that the nitrogen and phosphorus treatments given to the seed-plants affected the phos-

phorus, and, to a smaller extent, the nitrogen content of the seed. The other treatments did not significantly affect its N, P or K content. The mean yields of carrots from field sowings of four lots of seed of differing phosphorus content are shown in Table 2, where it can be seen that there was a positive correlation between yield and the phosphorus content of the seeds.

These results indicate that parent plant nutrition can affect the concentration of phosphorus in seeds, which in turn may affect plant yields. The slight decreases in the nitrogen contents of the seeds which were correlated with their increased phosphorus content seem unlikely to have caused the differences in their performance. Similarly, although the uptake of molybdenum by plants may be affected by their phosphorus nutrition<sup>5</sup>, the molybdenum content of the pea and cress seeds were all above the levels associated with deficiency of this element in seeds and did not appear to be appreciably affected by the supply of phosphorus to the parent plants.

There was no evidence of heritable change of the kind reported by Durrant<sup>3</sup>, although it was observed that plants grown from seed produced by phosphorus-deficient plants were more variable in size than those from non-deficient plants. Further experiments to determine the nature of this effect are in progress.

We thank Dr. E. J. Hewitt of the Research Station, Long Ashton, Bristol, for carrying out the molybdenum analyses of the seeds.

### Effect of X-irradiation on Changes of Cell Distribution Curve of Mouse Bone Marrow as detected by Electronic Particle Counting

THE Coulter counter has now been widely accepted as a blood counter in clinical laboratories. Favourable evaluations of the instrument for use as a cell-size analyser have been reported<sup>1-5</sup>. The principle, construction and operation of the counter have been described by Coulter in 1956 (ref. 6) and by Mattern *et al.* in 1957 (ref. 1). In brief, the counting and size analysing are based on electronic gating. Cells suspended in an electrically conductive medium are made to flow through a small aperture conducting an electric current between two electrodes. Each cell, being a poor conductor, displaces a certain amount of the conductive medium corresponding to the cell volume and consequently raises the impedance to the flow of electric current proportional to the amount of medium displaced. The resulting change in voltage across the aperture is recorded in threshold units by a decade counter and visualized on an oscilloscope screen.

With the aid of the Coulter counter we have examined the cell-size distribution of mouse femoral marrow from non-irradiated normal animals and the cell distribution changes in the marrow of irradiated animals.

LAF<sub>1</sub> male mice of 10-12 weeks of age purchased from Jackson Memorial Laboratory were used. The animals were divided into groups of five. Each group was given a different dose of whole-body X-irradiation (200 kVp., 20 m.amp, half-value layer, 1.35 mm copper), ranging from 10 r. to 800 r. (LD<sub>100</sub>). The animals were killed by an overdose of ether 24 h following irradiation. The femurs of each animal were excised. The two ends of the

femur were cut to expose the bone cavity in such a way that a minimum loss of marrow resulted. The marrow was blown out into a test-tube by injection of normal saline for intravenous injection from a 22 needle on a 10-ml. syringe. Ten femurs from five animals of the same experimental group were pooled together to make a total volume of 6 ml. cell suspension. The cells in clumps were freed by holding the thumb over the top of the tube and the index finger on the bottom and shaking 40 times in a strong, jerky action. The cells were then forced ten times through a 25-gauge needle on the same 10-ml. syringe. One ml. of the suspension was diluted with 99 ml. of normal intravenous saline. The diluted suspension was filtered through a layer of cotton of about 5 mm in thickness with a single ply gauze above and below the cotton. The filtered cell suspension was free of clumps under examination with a microscope. The process between the time of blowing the marrow out from the bone cavity and the time immediately before counting lasted about 15–20 min.

The Coulter counter model B was used for our experiments. Experimental setting of the counter were: amplification, 2; and aperture current, 0.707. The cells between 10 and 110 threshold units were counted in steps of five threshold units. The cells, mostly erythrocytes, between 5 and 10 threshold units were excluded from our experiments as they were mixed with a great deal of cell debris. Each count was repeated three times in order to minimize experimental errors. The mean of the three was used as the final count. Before each count, the aperture was cleaned with a brush and the suspension was stirred by bubbling air through a rubber tube into the suspension to prevent the precipitation of the cells. The results were calculated in percentage of cells for each step of five threshold units. The cell percentages were plotted against threshold units to form a cell distribution curve (Fig. 1). A comparison of the curves revealed that curves from animals exposed to the following radiation doses, 800, 600, 400, 200 and 100 r., differed from the standard curve of the non-irradiated animals in the 10–15 unit range; they had a much higher percentage of cells than that of the non-irradiated animals, and in the 30–70 unit range of the curve, the 30–70 unit section of the curve is shaped like a 'hump' in all the non-irradiated marrow. The 'hump' was greatly diminished in the marrow of the animals which were exposed to 100 r. or more. With the exception of the 10–15 unit section of the curve of 100 r., the remaining portions of the curves of the animals exposed to 100 r. or more differed very little from each other. The 10–15 unit section of the curve of 100 r. was half-way between the normal control and the 800 r. Marrow from animals exposed to 65, 50, 45, 40, 25 and 10 r. responded differently. Their cell distribution curves, including the 10–15 unit section and the 'hump', were similar to the curves of non-irradiated marrow. The diminution of the 'hump' at only doses of 100 r. or more, but not less, suggests that the response may be an 'all-or-none' phenomenon with a threshold somewhere around 100 r.

Since all the foregoing counting was done 24 h after irradiation, the possibility that the normal appearance of the curves of doses below 100 r. may have resulted from a fast recovery cannot be ruled out. For this reason, the marrow of animals exposed to 25, 40, 50 and 65 r. were also counted 1 h after irradiation. No change of the curve was observed. The 'hump' remained normal. These results suggest that after a critical dose of radiation the medium-sized cells suddenly diminish while the small cells increase.

These findings were rather surprising. As in our cellular dry mass examinations of bone marrow with non-irradiated animals and animals irradiated at various dose levels from non-lethal to supra-lethal, the results show that the cellular dry mass and the percentage of radiation-

Fig. 1. Note that the 'hump' appears in the curves of the unirradiated control, 25 r. and 65 r., but is greatly diminished in the curves of 100 r., 200 r., and 800 r. Not all the curves of the tested doses are presented here. Curves for 400 r. and 600 r. are almost identical with that of 800 r. and curves for 50 r., 45 r., 40 r., and 10 r. are similar to that of the control. Dotted lines indicate the baseline for each curve. Each division on the ordinate line represents 5 per cent of the cells counted. Cells of more than 80 threshold units are omitted from all the curves because they show little difference from each other.

induced giant cells increase with the increase of radiation dose<sup>7-9</sup>. We expected a parallel change in the cell-size distribution in the electronic counting. To reconcile the discrepancy, we believe that the distribution changes found in counting with a Coulter counter are not due to changes in cell-size, but due to changes in conductivity of the cell caused by cell membrane injury from irradiation, and that changes in conductivity of the cell are triggered off by a critical radiation dose. An increase in cell conductivity is recorded by the counter as a decrease in cell-size since the size of a cell is based on the low-conductivity of the cell and the volume of conductive medium displaced by the cell in the counting with a Coulter counter. This will explain why the 'hump' diminishes at a critical radiation dose-level with an accompanying increase of small cells at the 10–15 unit section of the curve.

Apart from the theoretical considerations, in the practical aspects these findings can be adapted as a test for rapid screening of nuclear irradiated victims from a large population. This test will indicate whether a person received more than a non-lethal dose of radiation (300 r. or below, in the case of *LAF<sub>1</sub>* mice). A person receiving doses below 100–200 r. scarcely requires immediate medical attention.

## MICROBIOLOGY

Mating in *Pseudomonas aeruginosa*

SEXUAL recombination in *Pseudomonas aeruginosa* was first reported by Holloway<sup>1</sup>. Later, Holloway and Jennings<sup>2</sup> demonstrated that there were similarities between their mating system and that of *Escherichia coli* K12. Fertility in the males was associated with an infectious factor which Holloway and Jennings called FP to distinguish it from the fertility factor, F, in *E. coli*. They were, however, unable to free their cells from the FP factor with acriflavine. Holloway<sup>1</sup> reported 125 recombinants per 10<sup>9</sup> parent cells.

Experiments were designed with the view of using the *Pseudomonas aeruginosa* mating system to assist genetic mapping of isoleucine-valine mutants. FP<sup>+</sup> and FP<sup>-</sup> strains were kindly provided by Dr. Holloway. We used FP<sup>+</sup> and FP<sup>-</sup> strains of strain 1 (1, try<sup>-</sup>, str<sup>r</sup>, chl<sup>r</sup>, FP<sup>+</sup> and 1, leu<sup>-</sup>, str<sup>s</sup>, chl<sup>s</sup>, FP<sup>-</sup>). Overnight cultures of these strains grown in Difco nutrient broth at 37° C were used for mating. The cells were washed once in saline and resuspended to the same concentration (approximately 10<sup>9</sup> cells per ml.). Equal volumes of FP<sup>+</sup> and FP<sup>-</sup> cells were mixed and 0.1 ml. aliquots of the mixture were spread on minimal agar plates of Davis and Mingioli<sup>3</sup> enriched with 0.005 per cent Difco nutrient broth. The plates were incubated at 37° C for 3 days and examined for the presence of prototrophic recombinant colonies.

Unfortunately when mating was carried out as described extreme variability was noticed between replicates from the same mating mixture as well as between mating mixtures prepared on different days. Some days we obtained up to 400 recombinant colonies per plate. On other days we obtained as few as 10 colonies per plate. 400 colonies represent one recombinant per 1.2 × 10<sup>5</sup> FP<sup>+</sup> cells.

During investigations of this variability we noticed one surprising result. In one experiment we mated a 10<sup>-1</sup> dilution of the FP<sup>+</sup> cells with undiluted FP<sup>-</sup> cells and obtained a mean of 386 recombinant colonies per plate with the diluted FP<sup>+</sup> cells but only 64 when the same cells were used undiluted. This observation was extended to include other dilutions of both FP<sup>+</sup> and FP<sup>-</sup> cells and the results of two experiments are set out in the following table. The experiments were carried out on different days and give a clear indication of the variability of the system. In Experiment I the FP<sup>-</sup> cells were diluted 10<sup>-2</sup> and used at that concentration. In Experiment II the FP<sup>+</sup> and FP<sup>-</sup> cells were diluted equally.

Table 1. RECOMBINANTS OBTAINED AFTER DILUTION OF PARENT FP<sup>+</sup> AND FP<sup>-</sup> CELLS OF *Pseudomonas aeruginosa*

	Dilution of FP <sup>+</sup> cells	Dilution of FP <sup>-</sup> cells	No. of recombinants per plate
Exp. I	No dilution	10 <sup>-2</sup>	0
	10 <sup>-1</sup>	10 <sup>-2</sup>	4
	10 <sup>-2</sup>	10 <sup>-2</sup>	79
	10 <sup>-3</sup>	10 <sup>-2</sup>	144
Exp. II	No dilution	No dilution	250
	10 <sup>-1</sup>	10 <sup>-1</sup>	255
	10 <sup>-2</sup>	10 <sup>-2</sup>	313
	10 <sup>-3</sup>	10 <sup>-3</sup>	100
	10 <sup>-4</sup>	10 <sup>-4</sup>	10

These results show that in Experiment I recombination was inhibited when the FP<sup>+</sup> parent was in gross excess and the number of recombinants increased as the number of FP<sup>+</sup> cells decreased. In Experiment II recombination was demonstrated with high concentrations of FP<sup>+</sup> cells provided the FP<sup>-</sup> cells were there in an equivalent concentration. It also shows that the system was much less efficient when there was an excess of both parents. A ten-fold decrease in the concentration of both parents from 10<sup>-2</sup> to 10<sup>-3</sup> resulted in only a three-fold decrease in the number of recombinants. It was only when the cells were diluted from 10<sup>-3</sup> to 10<sup>-4</sup> that the number of recombinants was correlated with the dilution.

Using the figure at the point of maximum efficiency we calculated the number of recombinants per FP<sup>+</sup> parent and found that the figure was greater than that recorded by Holloway<sup>1</sup>. In Experiment II, using the number of recombinants at 10<sup>-3</sup> dilution, we obtained one recombinant for every 500 FP<sup>+</sup> cells. As stated, results do vary from day to day and in one experiment we found one recombinant for 109 FP<sup>+</sup> cells or 0.92 per cent recombination. In the same experiment, 1.7 per cent recombination was obtained when an FP<sup>-</sup> strain was used which had a thiamine marker as well as leucine. 1.7 per cent recombination was obtained with the thiamine marker and 0.92 per cent with the leucine marker.

These results show that the efficiency of recombination in *Pseudomonas aeruginosa* is much greater than previously reported. The system cannot achieve this efficiency when there is an excess of the parent cells. It is not yet clear how the excess cells interfere with the process but the problem is being investigated and will form the subject of a separate communication.

## Magnesium Sulphate as Stabilizer during Liberation of Yeast and Mould Protoplasts

LIVING protoplasts can be produced from yeast and moulds through treatment with snail or microbial enzymes<sup>1-6</sup>, and numerous investigations have made it evident that the removal of the cell wall does not affect to any large extent most of the biochemical and biological activities of the microbial cell.

Investigations on the permeability of bacterial protoplasts provide evidence that the exchange of matter between the interior of the cell and the external medium is regulated by the cytoplasmic membrane. Similar work on fungi is sparse although investigations on fungal protoplasts have also given evidence of the presence of a semi-permeable but non-rigid membrane with the function of a permeability barrier in these organisms<sup>7</sup>. In intact cells of yeast or moulds the mechanical protection of the cell wall prevents the disintegration of cells suspended in water or in very dilute media. It is well known that if the cell wall is digested the delicate cytoplasmic membrane disintegrates unless an osmotic stabilizer is applied. This stability can be obtained by adding to the medium a substance that does not penetrate, or penetrates very slowly, into the protoplast, although in this connexion it might be worth emphasizing that the stability of free fungal protoplasts is affected by several other factors besides the osmotic pressure of the medium.

Most investigations on protoplast formation and physiology have been carried out in media of comparatively high osmotic pressure since this seems to be required for maintenance of structural integrity. The solute must not be able to penetrate the osmotic barrier of the protoplast at an appreciable rate if the solution is to give protection from lysis. The concentration of the solutes used as stabilizers varies largely; this phenomenon can be correlated to some extent with differences in internal osmotic pressure in different species.

A wide variety of stabilizing media has been used by different workers to obtain protoplasts from fungi. Media containing one of the following solutes have commonly been used: sucrose, maltose, fructose, rhamnose, sorbose, xylose, sorbitol, mannitol, polyethyleneglycol, 'Carbowax-

0.000', KCl, NaCl, and serum albumin, added to a buffer solution at pH between 5.8 and 6.8. The protoplasts lysed rapidly or slowly with other solutes, and they lysed immediately when placed in distilled water. However, mannose<sup>1,3</sup>, mannitol<sup>2</sup>, MgSO<sub>4</sub> (refs. 9 and 10) and KCl (ref. 2) have been preferred by most workers.

We have investigated the properties of some of these solutes using *Candida utilis* and *Fusarium culmorum* protoplasts not only as stabilizers but taking into consideration other important factors, such as the stimulatory effect of the solute on the lytic enzymes and the degree of bacterial contamination of the suspensions, this last factor being a very important one to try to avoid during mass biochemical protoplast preparations. We have concluded that magnesium sulphate at a concentration of 0.8 to 0.10 M is by far the best of all the stabilizers tested, yielding a stable protoplast suspension<sup>9</sup>. Using the MgSO<sub>4</sub> concentrations, it is very unusual to see any microbial contaminants during the experiments and it facilitates the performance of experiments which require long incubation periods. It has also been observed that when microbial enzymes (streptozymes<sup>8,10</sup>) are used the formation of protoplasts takes place more quickly in MgSO<sub>4</sub>.

### Induced Protection against Wildfire Disease in Tobacco Leaves treated with Heat-killed Bacteria

PLANT tissues infected with viruses and fungi are often protected against re-infection with the same or another pathogen<sup>1-4</sup>. Multiplication in the host tissues of micro-organism(s) of the primary infection appears to be a pre-requisite of these protective actions. Recently Loebenstein succeeded in inducing partial protection of the host against viral infection by treating the host tissues with the protein part of the infective virus particle<sup>5</sup>. This indicates that, at least in some cases, the multiplication of the pathogenic agent is not necessary for the development of the protective effect. A phenomenon somewhat similar to that observed by Loebenstein is described in the present report. It has been shown that the pretreatment of tobacco leaves by heat-killed bacteria induces protection against infection by *Pseudomonas tabaci* (Wolf and Foster) Stevens.

Washed suspensions of *Ps. tabaci* H 17 were used in the experiments. Cell numbers were adjusted densitometrically.

For pretreatment of tobacco tissues half-leaves were injected according to Klement<sup>6</sup> with *Ps. tabaci* cell suspensions kept in a boiling water bath for 5 min and the other halves of the same leaves with water ('con-

Fig. 1. Protection induced by heat-killed bacteria in a tobacco leaf against the wildfire disease. Left half: water control. Right half: tissue pretreated with heat-killed *Ps. tabaci* cells.

trol'). For infection, cell suspensions containing 10<sup>7</sup> bacterial cells/ml. were injected into the leaves.

As the most striking symptom of infection with *Ps. tabaci* was the gradual wilting of the host tissues the degree of protection could be expressed by determining the difference between fresh weight of leaf disks punched from half-leaves pretreated with killed bacteria and from control half-leaves at various intervals after infection.

Intact leaves of *Nicotiana tabacum* var. White Burley plants (4- to 6-leaf stage) were used throughout the experiments. Pretreatment of tobacco tissues was carried out by bacterial suspensions containing 10<sup>9</sup>, 10<sup>7</sup> or 10<sup>5</sup> heat-killed cells/ml. The leaves were infected with *Ps. tabaci* one day after pretreatment. Infected water-pretreated half-leaves wilted and turned yellow within 2 days after infection, and perished within about 6 days. By contrast, half-leaves pretreated with 10<sup>9</sup> heat-killed cells/ml. remained normal for 6 days after infection, that is, a marked delay in symptom development was experienced (Fig. 1). The protection induced by 10<sup>7</sup> or 10<sup>5</sup> heat-killed cells/ml. was less pronounced (Table 1). More efficient protection could be induced in young leaves than in older ones.

Fig. 2. Multiplication of *Ps. tabaci* in tobacco leaves treated with heat-killed cells of *Ps. tabaci*. A, Leaf injected simultaneously with heat-killed and living bacteria: —, half-leaf injected with living and heat-killed bacteria; — · — · —, half-leaf injected with living bacteria only. B, Leaf injected with living bacteria 1 day after pretreatment: —, half-leaf pretreated with heat-killed bacteria; — · — · —, half-leaf pretreated with water. Suspensions of 10<sup>9</sup> cells/ml. heat-killed cells (100° C for 5 min) and 10<sup>7</sup> cells/ml. suspensions of living bacteria were used for the injections.

\* Pretreatment of leaves was carried out by using cell suspensions of *Ps. tabaci* (10<sup>9</sup> cells/ml.) exposed to 100° C for 5 min.

† Infection was carried out by cell suspensions of *Ps. tabaci* containing 10<sup>7</sup> cells/ml.

‡ 0, 2, 4 and 6 days after infection.

All figures are averages of 3 samples.

The dependence of the degree of protection on the length of time elapsing between pretreatment and infection was also investigated. As may be seen from Table 2, time is needed for the development of protective action and this indicates the active part played by the host tissue in the process. Full effectiveness of the pretreatment is maintained only for a short period.

Treatment of tobacco leaf tissues with heat-killed bacteria failed to antagonize the effect of the toxin-containing culture filtrates of *Ps. tabaci*. These results suggest that the protective effect induced by heat-killed bacteria in the host is directed towards the living bacteria and not against their products. To test this idea investigations on the effect of pretreatment on the multiplication of bacteria in infected host tissues were undertaken. Determination of cell number was carried out by plate counting as described previously<sup>7</sup>. The results are shown in Fig. 2. It may be seen that bacterial multiplication was not affected by the heat-killed bacteria if the leaves were treated simultaneously with dead and living cells. On the contrary, the number of bacterial cells was less in half-leaves pretreated with heat-killed bacteria than in the controls until the fourth day after infection. Evidently, the pretreatment with heat-killed bacteria evoked unfavourable conditions in the tobacco leaf for the multiplication of *Ps. tabaci*. At the end of the experiment (6th day) cell number was already lower in the 'control' half-leaves than in those pretreated with bacteria. This is explained by the fact that the control half-leaves completely perished by that time and the bacteria were killed, whereas those pretreated with heat-killed bacteria were still free of symptoms and the multiplication of bacteria continued in these tissues at a low but constant rate.

Results of experiments obtained with bacteria exposed to 100° C for 5 or 15 min or for 2 h at 1 atm. pressure indicated that the latter drastic heat treatment results in a reduction of the protective effect which could be induced by heat-killed bacteria. This is probably due to a partial destruction of the cell component(s) responsible for this phenomenon.

Protection of tobacco leaf tissues against *Ps. tabaci* H 17 could be induced by heat-killed suspensions of other strains of *Ps. tabaci*, for example, *Ps. tabaci* H 20, *Ps. tabaci* T (a strongly toxin-producing strain) and by other species, for example, *Ps. syringae* 366 or *Corynebacterium flaccumfaciens* 1449. Evidently, the protective effect of heat-killed bacteria is not species specific.

The question arises as to the nature of physiological processes evoked by heat-killed bacteria in the host tissues. It can be assumed that the formation of phytoalexin-like inhibitory substances is involved<sup>8</sup>. However, further experiments are needed for the elucidation of this problem as it is also possible that the tissues pretreated with heat-killed bacteria are unable to provide substances or circumstances necessary for the optimal multiplication of *Ps. tabaci*.

### Modification of the Action of Ionizing Irradiation on *Escherichia coli* by 2-Fluoroadenosine

In the course of routine screening for radiation modifiers in bacterial systems, 2-fluoroadenosine<sup>1</sup> has been observed to modify the activity of ionizing irradiation on non-proliferating *Escherichia coli*. The procedures used to determine irradiation-modifying activity have been described<sup>2</sup>. In essence, the procedure used for measuring effects on non-growing cells consists of exposing washed

Fig. 1. 2-Fluoroadenosine (FAS) potentiation of the effect of ionizing irradiation ( $^{60}\text{Co}$ ) on non-proliferating cell suspensions of *Escherichia coli* 'ATCC 9637'.

cells (grown on simple glucose-salts medium and resuspended in M/15 phosphate buffer) to irradiation from a cobalt-60 source ( $\sim 1,000$  c., dose rate of 2.0 kr./min) with and without test compound. Experiments with growing cells were performed in which the test compound was added to the glucose-salts medium at the time of inoculation and aliquots of cell suspensions irradiated at varying times during the growth cycle.

Data compiled from several representative experiments which show the potentiating action of 2-fluoroadenosine on  $^{60}\text{Co}$ -irradiation damage of non-proliferating cells of *Escherichia coli* 'ATCC 9637' are presented graphically in Fig. 1. It may be noted that the effect is dose related.

Other non-proliferating wild-type cultures of *E. coli*, namely, *E. coli* 'B' (ORNL) and *E. coli* 'B' (Hill strain), responded differently from *E. coli* 'ATCC 9637' (see Table 1). 2-Fluoroadenosine potentiation of ionizing irradiation was not appreciable in *E. coli* 'B' (Hill), although it was observed in the derived radiation-sensitive strain, *E. coli* 'B<sub>s</sub>' (Hill)<sup>2</sup>. 2-Fluoroadenosine affords a modest degree of protection against the effects of ionizing irradiation on *E. coli* 'B' (ORNL), but the derived irradiation-resistant strain, *E. coli* 'B/r' (ref. 4), was more sensitive to ionizing radiation in the presence of 2-fluoroadenosine than in its absence. *E. coli* 'ATCC 11303' was slightly sensitive to potentiation by 2-fluoroadenosine.

Strains of *E. coli* 'ATCC 9637' resistant to either 2-fluoroadenosine, azaserine, 6-diazo-5-oxo-*l*-norleucine (DON), or nitrogen mustard<sup>5</sup> were found to be sensitive in

varying degrees to the potentiating action of 2-fluoroadenosine on ionizing irradiation when tested as cell suspensions. The strains resistant to 2-fluoroadenosine, azaserine, or nitrogen mustard were less sensitive than the parent culture, *E. coli* 'ATCC 9637', but the DON-resistant strain was approximately 100 times more sensitive than the parent culture. A culture derived from *E. coli* 'B' (Hill), resistant to the antileukaemic alkylating agent, 1,3-bis(2-chloroethyl)-1-nitrosourea<sup>6</sup>, was also more sensitive to the potentiating action of 2-fluoroadenosine on ionizing irradiation than its parent culture.

For potentiation to occur, 2-fluoroadenosine must be present during irradiation. Cell suspensions of *E. coli* 'ATCC 9637' were exposed to 0.1 mg of 2-fluoroadenosine per ml. for 1 h, washed three times by centrifugation, and irradiated. No increase in percentage killed of such cells, as compared to control cells, was observed.

The potentiating activity of 2-fluoroadenosine on ionizing irradiation damage of non-proliferating *E. coli* 'ATCC 9637' is not markedly affected by either cysteine or cysteamine (see Fig. 2). Cysteine (1.2 mg/ml.), for example, under the conditions described here, affords considerable protection to *E. coli* 'ATCC 9637' against an irradiation dose of 20 kr. (5.6 per cent survivors to 20 kr.; 47.6 per cent survivors to 20 kr. + cysteine, 1.2 mg/ml.). 2-Fluoroadenosine, 0.1 mg/ml., in combination with an irradiation dose of 20 kr., results in 0.08 per cent survivors. The combination of 2-fluoroadenosine, 0.1 mg/ml., with an irradiation dose of 20 kr. plus cysteine, 1.2 mg/ml., results in 2.97 per cent survivors. 2-Fluoroadenosine, 0.1 mg/ml., and cysteine, 1.2 mg/ml., either alone or in combination, are non-toxic to *E. coli* 'ATCC 9637'. Similar results were obtained with cysteamine.

The effect of 2-fluoroadenosine on *E. coli* 'ATCC 9637' under conditions which allow cell division, with and without ionizing irradiation, have been investigated (see Fig. 3). Non-toxic concentrations of 2-fluoroadenosine (0.1  $\mu\text{g}/\text{ml}$ .) do not appear to potentiate the damaging action of ionizing irradiation on this bacterium. A concentration of 2-fluoroadenosine which is bacteriostatic does potentiate irradiation effects.

Fig. 2. The effect of cysteine (1.2 mg/ml.) on the potentiation by 2-fluoroadenosine (FAS) of irradiation damage in non-proliferating cell suspensions of *Escherichia coli* 'ATCC 9637'.

## VIROLOGY

## Antigenic Variability of the Strains of Rous Sarcoma Virus

At present the variability of biological properties of the strains of the Rous sarcoma virus (RSV) is well known. This variability concerns first of all their oncogenic activity<sup>1,2</sup>.

Simons and Dougherty<sup>3,4</sup> were the first to note the antigenic differences between the three strains of RSV in the neutralization reaction. Moreover, antigenic differences were accompanied with considerable differences in biological properties<sup>1</sup>.

It has been shown that the Carr strain of RSV is able to cause haemorrhagic disease or tumours in rats<sup>5,6</sup>, rabbits<sup>7</sup> and other animals, including monkeys<sup>8</sup>. The Bryan strain exerted no oncogenic activity for mammals<sup>9</sup>. It was of interest to compare the antigenic properties of the two mentioned strains. The results of examining Carr and Bryan strains in the neutralization reaction with sera prepared against Carr strain follow.

The Carr strain was kindly supplied by Dr. G. Y. Svet-Moldavsky, and the Bryan strain by Prof. A. A. Smorodintsev. Both strains have been investigated for many years in the U.S.S.R. and are passed on chickens. The titres of virus in tumours were  $10^5$ – $10^6$  oncogenic doses ( $OD_{50}$ )/g tumour.

Thirty per cent tumour suspensions in Hanks's solution with 10 per cent calf serum were used as virus-containing material. The tumour suspensions were centrifuged twice at 3,000 r.p.m. for 20 min and the supernatant was kept at  $-50^\circ\text{C}$ .

The sera were taken from chickens the tumours of which, caused by RSV, had resolved. Before bleeding the chickens were given several additional injections of homologous RSV strain with an interval of 1–2 weeks.

The method of the neutralization reaction was as follows: 10-fold dilutions of virus suspension in saline were mixed with constant (1:5) dilution of test or control (normal calf) serum. The mixtures were incubated for 2 h at room temperature and 0.2 ml. was injected into the wing web of 2-week-old White Leghorn chicken (4–5 wing webs/mixture). The chickens were under observation up to 3 weeks. The neutralization index was calculated by the Reed-Muench method.

The results of a typical experiment where the serum against Carr strain distinctly neutralizes the homologous virus and is completely inactive against Bryan strain are given in Table 1.

The indexes of neutralization of Carr and Bryan strain by chicken sera against Carr strain are given in Table 2.

Table 1. RESULTS OF NEUTRALIZATION TEST OF RSV, CARR AND BRYAN STRAINS WITH CHICKEN SERUM NO. 9/2 AGAINST CARR STRAIN

Serum	Strain	Log of virus dilution				Neutralization index (NI)	NI (Carr) / NI (Bryan)
		2.5	3.5	4.5	5.5		
Immune	Carr	0/5*	0/5	0/5	0/5	$\geq 100$	
Control	Carr	5/5	5/5	0/5	0/5		
Immune	Bryan	4/4	4/4	2/4	1/4	0.3	$\geq 333$
Control	Bryan	5/5	5/5	1/4	0/4		

\* Numerator, No. of wing webs with tumours out of the No. of injected wing webs (denominator).

Table 2. INDEXES OF NEUTRALIZATION OF RSV, CARR AND BRYAN STRAINS BY IMMUNE CHICKEN SERA AGAINST CARR STRAIN

No. of the serum against Carr strain	No. of the test	Neutralization index (NI) of strain		NI (Carr) / NI (Bryan)
		Carr	Bryan	
9/2	1	$> 25$	$< 1.8$	$> 14$
9/2	2	$> 100$	0.3	$> 333$
9/5	1	10,000	3.15	3,200

7/2	3	1,000	0.5	2,000
7/5	1	1,000	0.3	3,333
4/5	1	1,000	1.8	556
10/5	1	1,000	1.0	1,000
4/2	1	10	0.25	40
4/2	2	12	8	1.5

Fig. 3. The effect of 2-fluoroadenosine (FAS) on the damaging effects of ionizing irradiation ( $^{60}\text{Co}$ ) on growing cells of *Escherichia coli* ATCC 9537. ●, Growth control; ○, 2-FAS, 0.1  $\mu\text{g/ml}$ ; △, 2-FAS, 1.0  $\mu\text{g/ml}$ ; ×, survivors to 30 kr.; □, survivors to 30 kr. + 2-FAS, 0.1  $\mu\text{g/ml}$ ; ■, survivors to 30 kr. + 2-FAS, 1.0  $\mu\text{g/ml}$ .

It has been reported<sup>7</sup> that cells deficient in purines have an increased sensitivity to the damaging effects of ionizing irradiation. The possibility that 2-fluoroadenosine exerts its irradiation-potentiating effect by inhibiting purine biosynthesis *de novo*—known to occur in non-proliferating *E. coli* ATCC 9637 (ref. 8)—was investigated. Cell suspensions of *E. coli* ATCC 9637 prepared from inocula grown in a glucose-salts medium supplemented with non-toxic (0.1–0.5  $\mu\text{g/ml}$ ) or slightly toxic (1.0  $\mu\text{g/ml}$ ) concentrations of 2-fluoroadenosine were no more sensitive to ionizing irradiation than were cell suspensions prepared from inocula grown in the same medium without 2-fluoroadenosine.

The mechanism by which 2-fluoroadenosine exerts its potentiating effect is unresolved. It is interesting to note, however, that under our conditions of test none of the following purine analogues affected the activity of ionizing irradiation on *E. coli* ATCC 9637: 6-mercaptopurine, 8-azaguanine, 8-azaxanthine, or 6-thioguanine. Surprisingly, 2-fluoroadenosine was also without effect.

From this table one can see that sera Nos. 9/2, 9/5, 7/2, 7/5, 4/5, 10/5 distinctly neutralize the homologous strain and are completely inactive against Bryan strain; serum No. 4/2 neutralizes weakly Carr strain and has no influence on Bryan strain. (The numerator of the number of the serum refers to the number of the chicken and the denominator shows the number of additional injections received by the chicken after the resolution of the tumour.)

The results obtained suggest that between Carr and Bryan strains there are distinct antigenic differences which are easily determined in the neutralization reaction. Thus, the principal differences between these two strains concerning their oncogenicity for mammals correspond to clear differences in the antigenic structure of virus protein.

We obtained preliminary results showing the wide antigenic variability of RSV strains: Bryan strain used in the work recorded here proved to be not identical with the standard Bryan strain obtained in 1964 through the courtesy of Dr. W. R. Bryan. The Schmidt-Ruppin strain also had its antigenic peculiarities.

Hanafusa *et al.*<sup>10</sup> showed that antigenic properties of RSV are due to the properties of the helper viruses pertaining to the avian leucosis complex. There are reasons for supposing that RSV strains which we have examined have not identical helper viruses.

As during the passage of RSV on chickens the strains can be contaminated by different avian leucosis viruses which are RSV helpers and which determine its properties, one of the mechanisms of RSV variability becomes clear.

Further investigations of antigenic variability of RSV are of great interest. They should lead to the serological classification of RSV and helper virus strains.

## Antibacterial Activity of a Variety of Viruses

It has been previously noted that growth of a number of bacterial species is inhibited *in vitro* by herpes simplex virus propagated in a variety of antibiotic-free cell lines<sup>1</sup>. 0.1 ml. of such tissue culture fluid, applied to 1 cm<sup>2</sup> of sterile thick filter paper, placed on a Petri plate surface-seeded with 0.2 ml. of a standardized inoculum of a 6-h bacterial culture on a medium containing equal parts of mixed 1 per cent trypticase in 2 per cent agar and monkey kidney B medium Melnick, was found to produce a distinct inhibitory zone around the virus-impregnated filter square with bacterial strains belonging to a number of different species after 16–18 h incubation at 37° C, providing sufficient concentration of virus is present. Allantoic fluid derived from 9-day-old chick embryos the chorioallantoic membranes of which had been infected with 2 herpes simplex virus strains failed to suppress the bacterial growth. Control tissue culture fluid, not inoculated with virus, was similarly ineffective in this regard.

A number of other viral species, randomly selected from among available stock without regard to titre, have been tested for antibacterial capability by the same procedure as an extension of the foregoing observation. These were propagated in antibiotic-free WI-38 human embryonic lung cell line and in some instances in the allantoic cavity of the chick embryo in order to ascertain whether or not viruses derived from a source other than tissue culture might also exert the same effect.

As may be noted in Table 1, some of the viral species did prove to be capable of inhibiting growth in a number of strains belonging to a variety of bacterial species, as evidenced by the production of a clear zone of varying diameter around the virus-impregnated filter paper square. Included among those which were active were some viruses which had been propagated in the allantoic cavity of the chick embryo. The possibility that some of the ineffective viruses might have proved to be active had they been of higher titre must be given consideration. Control tissue culture fluid and allantoic fluid were inactive. Thus, bacterial inhibition is a capability possessed by a number of different viruses including some cultivated in the allantoic cavity of the chick embryo as well as in tissue culture and is not limited to herpes simplex virus grown in tissue culture.

With regard to relative effectiveness of the different viruses, the broad activity of influenza strain PR8 and of the influenza A2 strain in eliciting bacterial inhibition is particularly noteworthy. As for the bacterial species involved, a high degree of refractoriness to viral inhibition may be particularly observed with all 5 *Pseudomonas aeruginosa* strains as well as with the 5 *Streptococcus faecalis* strains. The former was resistant to the entire gamut of test viruses as was the latter with the exception of some

of the influenza viruses. One *Staphylococcus aureus* and one *Aerobacter aerogenes* were also unaffected by any of the viruses. The reason for the refractoriness of some bacterial species and strains as well as the underlying mechanism responsible for the ability of viruses to effectuate bacterial inhibition remains to be elucidated.

This investigation was supported by U.S. National Science Foundation grant GB-2505.

### Further Simplification of the Purification Procedure of Influenza Virus on Barium Sulphate

A METHOD for the purification of influenza virus by adsorption to and elution from BaSO<sub>4</sub> with subsequent ultracentrifugation of the eluate has been published by Mizutani<sup>1</sup>. We have found that this method can be further simplified by separation of the citrate (necessary for elution but interfering with adsorption) in the form of its calcium salt after elution from BaSO<sub>4</sub> has been achieved. By this step the ultracentrifugation of the eluate is eliminated and repeated purification cycles on the BaSO<sub>4</sub> can be performed.

Allantoic fluid of eggs was infected with PR8, Singapore, and Lee strains of influenza virus maintained in this Institute. CCA was established according to Salk<sup>2</sup>, and infectivity by titrating serial dilutions of the preparations in embryonated eggs; N was determined by the Kjeldahl method as modified by Schulek<sup>3</sup>. In the adsorption stage the prescriptions of Mizutani were strictly adhered to but the time needed for adsorption was reduced to 1 h after it had been confirmed that during this period the virus content in the supernatant did not decrease, that is, the adsorption to BaSO<sub>4</sub> was complete. CaCl<sub>2</sub> solution, in quantities equivalent to the citrate content, was added to the eluate, the pH of which was adjusted to 7.2. After standing for 1 h in a refrigerator at 4° C Ca-citrate crystals separated. According to confirmatory tests these did not adsorb the virus. After sedimentation of the crystalline material by centrifugation a second cycle of adsorption to and elution from BaSO<sub>4</sub> could easily be carried out in the supernatant. The results are shown in Table 1.

It can be seen that in the case of the PR8 strain the results are similar to those of Mizutani. With the other two strains, however, the rate of recovery and the effi-

ency of purification were considerably lower. Mizutani's findings also indicate that the CCA/N value of strain 'Adachi' is five times greater than that of strain 'Setagaya'. Obviously differences concerning adsorption to and elution from BaSO<sub>4</sub> do exist between different strains. The data presented in Table 1, however, reveal that these differences are likely to originate from the different adsorptive capacity of the various strains to BaSO<sub>4</sub>. Thus adsorption to and elution from BaSO<sub>4</sub> show a similar pattern to the adsorption to and elution from Al(PO<sub>4</sub>) used by Miller and Schlesinger<sup>4</sup>. Some damaging effects on the adsorption of the yet unknown ballast substances in the allantoic fluid were also noted. There is no doubt that the peculiarities of the behaviour toward an adsorbent are determined by the surface of the viral particles, and might be changed by its variations.

The N/CCA values of the PR8 strain shown in Table 1, representing the efficiency of the purification process, compare favourably with the corresponding values found by Miller with his purest influenza virus preparations without substantial loss of infectivity. In view of the simplicity, effectiveness and technological advantages of autoclaving the adsorbent and eluent, further investigation of some other factors, such as pH, ionic strength, etc., influencing the adsorption to and elution from BaSO<sub>4</sub> of the various influenza virus strains seems to be justified.

## CYTOLOGY

### Chloroplast Replication: Evidence for 5-Bromouracil Incorporation and Plastid Mutation in *Euglena gracilis*

THERE is now growing experimental support for the hypothesis that nucleoprotein genetic determinant located outside the nucleus confer photosynthetic activity on plastids. The first clear indication of nucleoprotein involvement in plastid mutation was derived from the action spectrum for ultra-violet inactivation of *Euglena* plastids which showed peaks at 260 and 280 mμ. The ultra-violet sensitive plastid determinant is photoreactive<sup>1</sup>, and evidence for its cytoplasmic nature has been reported<sup>2-3</sup>. Comparison of wild-type and ultra-violet induced mutants of *Euglena* strongly suggests that DNA of different base composition from the nucleus is uniquely associated with the ability to form plastids. Similar findings have been reported for plastids of other algae<sup>4-8</sup> and higher plants<sup>9,10</sup>. The recent observation that cells which incorporate azathymine in place of thymine exhibit increased resistance to ultra-violet inactivation of plastids is consistent with the report that plastids have associated with them a specific DNA and serves as a guide to the rational search for chemical agents that might be expected to induce plastid mutations. By analogy with other nucleoprotein genetic systems, we have postulated that incorporation of base analogues into the genetic material that determines plastids should lead to mutational changes, and that such changes would be reflected in altered plastid structure and function. This communication presents evidence for incorporation of 5-bromouracil into cells of *Euglena gracilis*, and describes conditions for obtaining stable colourless plastid mutants during replication of plastids.

eterminants in the presence of 5-bromouracil and sulphanilamide.

The mutagenic effect of base analogues is strongly dependent on the concentration of the natural base, and mutagenesis can be observed only when the synthesis of the natural base is suppressed. For maximum incorporation of 5-bromouracil, cells of *Euglena gracilis* Z were grown in the presence of sulphanilamide in a sugar-containing medium<sup>11</sup> supplemented with a combination of metabolites (Table 1) to satisfy deficiencies induced by sulphanilamide. Preliminary experiments were performed to determine the optimum concentrations of sulphanilamide and bromouracil (Tables 2 and 3). The results indicate that growth is completely suppressed at concentrations more than 30 mg per cent sulphanilamide, and that at lower levels of sulphanilamide, growth could be restored by addition of *p*-aminobenzoic acid. When the concentration of sulphanilamide was lowered to 15 mg per cent, addition of 5-bromouracil partially reversed the growth inhibition, but not as effectively as *p*-aminobenzoic acid. Fig. 1 shows the growth response of *Euglena* to sulphanilamide alone and in combination with 5-bromouracil. It is apparent that the presence of the analogue permits considerably more growth than with sulphanilamide.

Colourless mutants of *Euglena* were first observed when cells grown in darkness with sulphanilamide and 5-bromouracil were plated on a basal medium (not containing either bromouracil or sulphanilamide). Under these conditions the frequency of mutant colonies which appear

2. Sulphanilamide 3 mg %	0.2	1.0
3. Sulphanilamide 10 mg %	0.1	0.2
4. Sulphanilamide 30 mg %	0.0	0.0

Cell growth measured as optical density was determined with a Bausch and Lomb Spectronic 20 colorimeter at 550 mµ after 7 days in continuous light at 25°-28° C.

Table 3. EFFECT OF 5-BROMOURACIL AND SULPHANILAMIDE ON THE GROWTH OF *Euglena gracilis*

Additions to complete medium	No addition	Sulphanilamide 15 mg %
1. No addition	2.5	0.1
2. 5-Bromouracil 50 mg %	4.9	0.1
3. 5-Bromouracil 200 mg %	2.4	0.6
4. <i>p</i> -Aminobenzoic acid 10 µg %	3.0	2.1

Cell growth measured as optical density was determined with a Beckman spectrophotometer model B at 550 mµ after 14 days in continuous light at 25°-28° C. The inoculum consisted of 3-day-old light-grown cells (100 cells/ml) grown in basal medium.

Table 4. EFFECT OF 5-BROMOURACIL ON THE FREQUENCY OF STABLE COLOURLESS MUTANTS OF *Euglena gracilis*

Additions to complete medium	Average No. of mutant colonies (%)	Range (%)	Total No. of colonies scored
No addition	0.7	0-3.4	1,175
5-Bromouracil 200 mg %	0.7	0-2.7	772
Sulphanilamide 15 mg %	1.4	0-5.7	755
5-Bromouracil 200 mg % + sulphanilamide 15 mg %	8.3	3.2-15.0	568

Experimental conditions: the inoculum consisted of 3-day-old light-grown cells (1,000 cells/ml.). After 14 days incubation at 25°-28° C in darkness approximately 100 cells in 0.1 ml. were spread on basal medium + 2.0 per cent agar plates using the overlay method described by Lyman *et al.*<sup>1</sup>.

as white or yellow-white, when plated, markedly increases above the spontaneous level. Table 4 summarizes the results of several experiments designed to determine the contribution of 5-bromouracil and sulphanilamide to plastid mutagenesis. The frequency of plastid mutants observed with either 5-bromouracil or sulphanilamide falls within the range of spontaneous mutation; however, in the presence of both the analogue and sulphanilamide, the mutant yield was considerably above the spontaneous level. A large number of these plastid mutants have been isolated, replated, and have thus far maintained their mutant identity through numerous sub-cultures. Analysis of mutant production in actively growing cells as compared with cells in resting medium provides evidence that plastid mutagenesis is strictly dependent on replication in the presence of 5-bromouracil and sulphanilamide; the mutant frequency of resting cells exposed to otherwise mutagenic conditions appears to fall within the spontaneous range.

The reversal of sulphanilamide inhibition by 5-bromouracil and the increased frequency of plastid mutants produced from cells grown in the presence of 5-bromouracil and sulphanilamide can be taken as evidence of incorporation of the analogue. Appearance of colourless plastid mutants (presumably lacking photosynthetic pigments such as chlorophylls) that do not revert to the normal green condition when grown in the absence of sulphanilamide or 5-bromouracil provides experimental support for their genetic stability. The observation of plastid mutation associated with 5-bromouracil incorporation is consistent with the hypothesis that plastid replication is under the control of a DNA that is susceptible to genetic alteration by base analogues.

The mutagenic effect of base analogues such as 5-bromouracil has been attributed to base pair transitions<sup>12</sup>. According to this view, incorporation of the analogue *per se* is insufficient to cause mutagenesis, and requires replication of the DNA strand containing the 5-bromouracil<sup>13</sup>. That induction of plastid mutagenesis is dependent on growth in the presence of 5-bromouracil and sulphanilamide argues in favour of a plastid determinant that must be replicated for the mutagenic event to occur, and suggests that the mechanism of base analogue mutagenesis of the plastid genome may parallel that proposed for other DNA-containing genetic systems.

## FORESTRY

### Pathways of Water Movement in Young Conifers

EXPERIMENTS on the uptake of dyes by conifers have suggested that water is transported vertically in the earlywood of the annual ring<sup>1</sup>. Few systematic investigations have been made, however, to determine how this pattern of water movement is achieved, whether there is any lateral transport between the earlywood regions of different annual rings or, indeed, whether this pattern is constant under different environmental conditions.

A series of experiments has been made in the greenhouse on young plants of Corsican pine (*Pinus nigra* var. *calabrica* Loud.), Japanese larch (*Larix leptolepis* Murr.), Norway spruce (*Picea abies* L. Karst.) and Scots pine (*Pinus sylvestris* L.), up to 4 years of age, to determine the pattern of water transport in roots, stems and twigs under different environmental conditions. The effective water-conducting tissues were identified by immersing whole root systems or individual roots of intact plants in aqueous solutions of various dyes, including acid fuchsin, reduced basic fuchsin and safranin. Experiments were made on actively transpiring plants and on plants in which transpiration was reduced by enclosing the shoots in perforated polythene bags.

After immersion in the dye for periods of 1-5 days, the plants were dissected and cross- and longitudinal-sections made at intervals along the roots, main stem and major branches: these sections were rapidly washed in 95 per cent ethyl alcohol, washed twice in absolute alcohol and finally mounted in Canada balsam.

For detailed investigations acid fuchsin proved unsuitable since it did not adequately stain the xylem walls and often diffused out after the sections were cut. In contrast, 0.1 per cent basic fuchsin that had been almost decolorized with 10 per cent sodium metabisulphite<sup>2</sup> stained the xylem walls intensely and did not usually diffuse out. When freshly cut sections of stems that had not previously been treated with the dye were immersed in reduced basic fuchsin, both the xylem and phloem showed a marked affinity for the dye. The observation that the intensity of staining of such sections in weak solutions of the dye (0.1-0.001 per cent) appeared to be a function of the length of exposure to the dye offered, in addition, a semi-quantitative measure of dye uptake. For example, examination of sections of branches at various heights on the main stem showed a higher intensity of staining in the xylem of lower whorls than of upper ones, indicating, therefore, a greater velocity of flow through the lower

branches. This may have been due to the very much larger number of needles on the lower whorls.

In young plants with up to four annual rings, all or most of these rings were concerned with water transport, and generally this occurred mainly in the earlywood of each ring. In short-term experiments the latewood was commonly not stained at all. This pattern of upward movement of water along a series of concentric earlywood circles confirms the findings of Harris<sup>1</sup> based on the uptake of safranin by seedlings of *Pseudotsuga taxifolia*, *Pinus nigra* and *Pinus radiata*. Our investigations suggest, however, that there is no sharp differentiation in the pathway of water transport within an annual ring. Observations of a grading off in dye intensity from the larger diameter, earlywood cells to the smaller diameter, latewood cells indicate a gradual decrease in the rate of translocation as the component tracheids decrease in size within the annual ring. Under conditions of low transpiration, less of the annual ring was involved in water transport than when transpiration was high. That smaller elements may be brought into use for the conduction of water under conditions of high transpiration is supported by Scholander's<sup>3</sup> observations that upward water movement in trees follows a path of least resistance; when larger elements were blocked by air, water moved through smaller ones.

In most of our experiments, the medullary rays were very heavily stained with dye, suggesting a highly efficient radial conduction of water; in some cases the dye was seen throughout most of the ray extending across the latewood of the outermost annual ring into the phloem ray cells. In contrast, tangential movement of water from the rays into the latewood of the annual ring appeared to be limited by restricted transport within the latter. Staining usually was observed only in the single row of latewood tracheids adjacent to the ray.

Examination of cross and longitudinal sections of treated plants below the root collar revealed that the separation of the vertical water path into concentric circles, such as was observed in the stem, had already occurred below ground; in other words water was conducted from the root in more than one annual ring.

## OCEANOGRAPHY

### Slicks associated with *Trichodesmium* Blooms in the Sargasso Sea

NATURAL slicks are apparently formed by the rippling damping action of monomolecular layers of organic matter which have an effective strength of only a few dynes/cm or less and are visible against the adjacent rippled water only in relatively calm weather<sup>1-4</sup>. One of the few correlations of slick with source was made by Grantved<sup>5</sup> when an oily slick of several square miles in the North Sea was found to contain a high oily, senescent and dense patch of the diatom *Coscinodiscus concinnus*. The existence of blue-green algae of the genus *Trichodesmium* in the open ocean<sup>6</sup>, and its wide distribution<sup>7</sup> and ability to discolor

water as well as some of its ecology<sup>9,10</sup> has long been recognized. The purpose of this communication is to describe blooms in which well-defined and surfactant slicks were associated with dense patches of *Trichodesmium* species.

During R.V. *Trident* cruise 10 (September 7-20, 1963) in the Sargasso Sea to continue an investigation<sup>11</sup> of the pelagic Gulf weeds, two marked areas of surface slicks were observed. The water, both rippled and slick, lacked the usual clarity of tropical oceanic water. The presence of brownish-red specks appeared more prevalent in the slick areas. An examination of bucket samples revealed the presence of two species of *Trichodesmium* which were more abundant in the slick areas than in the adjacent rippled waters. The dominant organism was *Trichodesmium erythraeum* Ehrenberg ex Gomont (*Skujaella erythraea* (Ehrenberg) De Toni); *Trichodesmium thiebautii* Gomont (*Skujaella thiebautii* (Gomont) De Toni) was also present.

The slicks ranged in size from about 75 m ovoid patches (area 1: 30°19' N, 60°08' W) to long windrows approximately 0.25 km by 3 km (area 2: 33°19' N, 63°05' W). These slicks were observed over a distance of some 200 km in both areas. Since a series of spreading oils of the Adam's variety<sup>12</sup> prepared and calibrated by the Surface Chemistry Branch of the U.S. Naval Research Laboratory, Washington, D.C., were aboard, an attempt was made to determine if the slicks were associated with surfactant activity. Some vials dipped in the calibrated oils were thrown ahead of the bow and the equilibrium spreading pressures of the mid-portion of rippled and slick areas were noted. Bucket samples were taken from the other side of the ship and 375-ml. aliquots were used to determine the algal and bacterial content. Three samples of each water type in area 1 and six samples of each type in area 2 were examined. Due to the variable number of filaments in each *Trichodesmium* bundle (usually 12-23 with an extreme of 80) the bundles were teased and the number of filaments were counted. Bacterial counts were obtained from surface inoculated sea water agar plates incubated at 27° C for three days. The results are given in Table 1. There was a small but measurable increase in the equilibrium spreading pressure in the slick areas. The apparent concentration of *Trichodesmium* in the slick areas was confirmed.

Table 1. COMPARISON OF EQUILIBRIUM SPREADING PRESSURE (E.S.P.), *Trichodesmium*, AND BACTERIAL POPULATIONS IN RIPPLED AND SLICK SURFACE WATERS OF BLOOM AREAS OF THE SARGASSO SEA\*

		1-2, 3-3-4-5	69, 172	

\* Mean of three observations per water type in area 1 and of six in area 2.

Although the bacterial counts were higher in the slicks of area 1 there was neither marked enhancement nor inhibition of the natural population. Since blue-greens have been noted for their inhibitory activities<sup>13,14</sup> a plankton net concentrate from area 1 (with gross zooplankton removed, filtered on a clean towel to give approximately 0.5 g algal cells, and ground with 1 ml. of sterile sea water) was filter pad assayed against a strain each of *Achromobacter*, *Pseudomonas*, *Vibrio* and *Sarcina*. There was only minimal activity against the *Vibrio*, which is the dominant genus found associated with algal material. Agar plate enzyme assays on the same material for lipase, gelatinase and amylase showed marked activity for the latter. The results are given in Table 2. This activity against a polysaccharide is of interest due to the known

Table 2. THE ENZYMATIC AND ANTIBACTERIAL ACTIVITIES OF A *Trichodesmium* CELL CONCENTRATE (1:3 DILUTION W/V)

Enzyme activity	Antibacterial activity
Zone mm	Zone mm
Lipase ('Tween-80')	<i>Sarcina</i>
Gelatinase	<i>Pseudomonas</i>
Amylase	<i>Achromobacter</i>

	1-0

ability of blue-greens to excrete appreciable quantities of these substances<sup>15,16</sup>. It seems possible that the slicks associated with *Trichodesmium* may be due at least in part to the surfactant property of excreted carbohydrates.

The occurrence of large blooms of *Trichodesmium* in tropical and subtropical oceanic waters and the ease of its detection and handling may make it an ideal test organism for examining the algal excretion of organic compounds and their role in surface slicks.

## STATISTICS

### An Epidemic Process in an Open Population

In general an epidemic process can be characterized as a time-dependent process of transition by the members of a population, where the state transitions are caused by exposure to some influence called infectious material. The members of the population can belong to one of three basic states at a given point in time: (a) *Infective*, those members of the population who are host to the infectious material; (b) *Susceptible*, those members of the population who can become infectives given effective contact with infectious material; (c) *Removal*, those members of the population who have been removed from circulation for one of a variety of reasons such as death, immunity, hospitalization, etc.

These latter members may have been either susceptibles or infectives at the time of their removal.

As the process develops, an individual is exposed to infectious material either by direct contact with an infective or through some intermediary host or vector. The exposed person may either be resistant to the incoming organism, in which case the organism is rejected, or may be infected by it, in which case the invading organism proceeds on a course of development. The time-interval in which the development takes place is called the latency period, that is, the interval of time necessary for a susceptible to be transformed into an infective. In other words the latency period is the time-interval between the receipt of infectious material by a susceptible and the time at which he is in a position to transmit infectious

material to another susceptible, thus repeating the process.

There has been extensive development of mathematical representations of epidemic processes<sup>1,2</sup>. Such a process may be treated deterministically, in which case it can be represented by a system of differential equations; or it may be treated stochastically, in which case the process is represented by a finite state Markov process of either discrete or continuous parameter depending on the physical situation. (The discrete parameter is applicable where the latency period is constant, in which case infectives occur in generations.)

Mathematical treatments of epidemic processes, both deterministic and stochastic, which have appeared in the literature have usually dealt with processes involving closed populations; that is, a population  $N$  which remains constant throughout the development of the process.

The purpose of this note is to point out a property of an epidemic process in which the population is open; that is, in which  $N$  is not constant. In such a process new supplies of susceptibles and infectives are introduced into the population as the process proceeds on its course of development.

Consider a population  $N$ , consisting of  $S$  susceptibles,  $I$  infectives, and  $R$  removals, and in which the infectious material is transferred by direct contact.  $N$ ,  $S$ ,  $I$ , and  $R$  are all functions of time  $t$ . Let  $\beta$  be the rate of infection in  $N$  and  $\gamma$  the rate of removal of both susceptibles and infectives. (Although this assumption may not be very realistic in describing the spread of infectious disease, it may be realistic in the treatment of other physical situations as epidemic processes, particularly the information spread<sup>3</sup>.) Let  $\mu$  be the rate at which new susceptibles are introduced into  $N$  and let  $\nu$  be the rate at which new infectives are introduced.

If homogeneous mixing among members of the population and a zero latency period are assumed, the process can be described deterministically by the following system of differential equations:

$$\begin{aligned} \frac{dS}{dt} &= -\beta SI - \gamma S + \mu \\ (E) \quad \frac{dI}{dt} &= \beta SI - \gamma I + \nu \\ \frac{dR}{dt} &= \gamma(S + I) \end{aligned}$$

A threshold density of susceptibles can be obtained if initial conditions of a single infective introduced into the population at time  $t_0$  is assumed. Hence:

$$N_0 = S_0 + 1$$

That is, the initial population  $N_0$  consists of  $S_0$  susceptibles, one infective, and zero removals.

For an epidemic to develop from time  $t_0$  the rate of change of the number of infectives must be positive. Hence:

$$\begin{aligned} \beta S_0 I &> \gamma I - \nu \\ \text{or} \\ S_0 &> \frac{\gamma - \nu}{\beta} = \rho \end{aligned}$$

Thus an epidemic can develop from time  $t_0$  only if the number of initial susceptibles  $S_0$  exceeds the threshold  $\rho$ .

By the existence and uniqueness theorems for systems of ordinary differential equations<sup>4</sup>, a solution to the system (E) exists and is unique.

$R$  can be obtained by direct integration as follows:

$$\begin{aligned} \text{Since } N &= S + I + R \\ \frac{dR}{dt} &= \gamma(N - R) \end{aligned}$$

$$\text{and } \frac{dR}{dN} = \lambda(N - R) \quad \text{where } \lambda = \frac{\gamma}{\mu + \nu}$$

$$\text{Then } R = \frac{(\lambda N - e^{\lambda N}) + e^{\lambda N_0}(1 - \lambda N_0)}{\lambda e^{\lambda N}}$$

$$\text{or } R = \frac{(\gamma t + \lambda N_0 e^{\gamma t}) + (1 - \lambda N_0)}{\lambda e^{\gamma t}}$$

$$\text{and } S + I = \frac{e^{\gamma t} + \lambda N_0 - 1}{\lambda e^{\gamma t}}$$

This process will reach its peak at the point in time for which the rate of change of susceptibles and infectives is maximal.

$$\text{Hence: } \frac{d^2(S + I)}{dt^2} = 0$$

in order for the process to peak.

Now

$$\frac{d^2(S + I)}{dt^2} = \frac{[\gamma N_0 - (\mu + \nu)]\gamma}{e^{\gamma t}}$$

Hence:

$$\frac{d^2}{dt^2}(S + I) = 0$$

either for  $t = \infty$  or when  $N_0 = \frac{\mu + \nu}{\gamma}$

but the  $\lim_{t \rightarrow \infty} (S + I) = \frac{\mu + \nu}{\gamma}$

Thus if the process attains a peak and stabilizes itself the number of susceptibles and infectives at its initial point will equal the number of susceptibles and infective at its terminal point.

In fact from the system of equations (E) it can easily be seen that in this event:

$$S + I = \frac{\mu + \nu}{\gamma}$$

for all values of  $t$ .

Hence the process (E) will reach a maximum in finite time if, and only if, the sum of susceptibles and infective is constant.

In the general case, that is, where  $\delta \neq \gamma$  is the rate of removal of susceptibles, it follows directly from the system of differential equations that if

$$\frac{d^2(S + I)}{dt^2} = 0$$

then  $\frac{dR}{dt} = \delta S + \gamma I$  equals a constant. But if  $\delta S + \gamma$

equals a constant then  $\frac{d(S + I)}{dt}$  equals a constant

Hence  $\frac{d^2(S + I)}{dt^2} = 0$  and

**Theorem 1.** The general process (E) will reach a maximum in finite time if, and only if, the rate of change of removals is constant.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, February 22

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Prof. Emrys Jones: "The London Atlas".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. J. A. Saxton, Mr. J. A. Lane, Mr. R. W. Meadows and Mr. P. A. Matthews: "Layer Structure of the Troposphere".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. H. S. Kaplan (Stanford): "Unfolding Concepts of Mechanisms in Leukemogenesis and Carcinogenesis".\*

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Transport in the Year A.D. 2000".

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUBGROUP (at the Eccleston Hotel, London, S.W.1), at 7.30 p.m.—Mr. R. Calvert: "Curing Systems".

## Tuesday, February 23

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. L. L. Jones and Mr. G. D. Base: "Test of a One-Twelfth scale Model of the Dome Shell Roof for Smithfield Poultry Market"; and Mr. P. Ahm and Mr. E. J. Perry: "The Design of the Dome Shell Roof for Smithfield Poultry Market".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "What is systems Engineering?" opened by Mr. K. L. Smith.

SOCIETY OF INSTRUMENT TECHNOLOGY (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. J. Avery: "Automatic Instrument manufacture".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. I. M. Glynn: "The Transport of Sodium and Potassium Across Cell Membranes". (Twelfth of sixteen lectures on "The Scientific Basis of medicine" organized by the British Postgraduate Medical Federation.)\*

INSTITUTION OF MECHANICAL ENGINEERS, GRADUATES' AND STUDENTS' SECTION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.30 p.m.—Dr. C. Wright: "Design and Development of Modern Guns".

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. R. A. Shaw: "Some aspects of Non-Metallic Inorganic Polymers".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at Norwood Technical College, Knight's Hill, Norwood, London, S.E.27), at 7 p.m.—Lt.-Col. B. D. Haw: "Explosives".

## Wednesday, February 24

ROYAL SOCIETY OF MEDICINE (joint meeting with the Society for Endocrinology, at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 10 a.m.—Meeting on "Salt and Water".

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 2 p.m.—Dr. H. E. M. Kay: "Possibilities of Transplantation of Bone Marrow".\*

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY AND FOOD GROUPS (at the School of Pharmacy, University of London, Brunswick Square, London, W.C.1), at 2.30 p.m.—Meeting on "Modern Trends in Food Preservation".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. M. Kaufman: "New Plastics and Their Application".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. M. Cowan and Mr. L. L. Preston: "Parallel Operation of Transformers with On-Load Tap Changes and Negative-Reactance-Compounding Control".

UNIVERSITY OF LONDON (at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2), at 5.30 p.m.—Dr. S. R. Pele: "Electron Microscope auto-Radiography". (Second of three lectures on "The Scientific Basis of entistry" organized by the British Postgraduate Medical Federation.)\*

INSTITUTE OF METALS (at 17 Belgrave Square, London, S.W.1), at 6 p.m.—Prof. W. D. Robertson (Yale University): "Design Criteria for the Development of New Alloys".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, TELEVISION GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Meeting on "A Low Cost Video Tape Recorder for Professional Applications".

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. H. F. Padbury: "Oxygen Steelmaking processes: Consideration of Some Operational and Engineering Aspects" (first John Player Lecture).

INSTITUTION OF ENGINEERING INSPECTION (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.15 p.m.—Mr. E. Newton: "Investigation of Aircraft Accidents—The Engineering and Inspection aspects".

OFFICE OF HEALTH ECONOMICS (at the Royal Society of Health, 90 Buckingham Palace Road, London, S.W.1), at 8.30 p.m.—Dr. J. Yule Bogue: "The International Pattern of Pharmaceutical Research".\*

## Thursday, February 25

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 a.m.—Mr. D. Brennan, Mr. M. J. Graham, Mr. F. H. Hayes and Mr. D. O. Hayward: "The Energy and Configuration of the Adsorbed Layer with special reference to the Adsorption of Krypton, Xenon, Carbon Monoxide and Carbon Dioxide on Metals".

INSTITUTION OF CIVIL ENGINEERS, HYDROLOGICAL GROUP (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Informal Discussion on

"The Hydrological Aspects of the Work of the Water Resources Board" introduced by Mr. N. A. F. Rowntree.

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. I. S. Longmuir: "Tissue Oxygen Requirements". (Thirteenth of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)\*

CHEMICAL SOCIETY (in the Edward Lewis Lecture Theatre, Middlesex Hospital Medical School, London, W.1), at 6 p.m.—Prof. F. Lynen: "Biosynthesis and Function of Biotin-Enzymes" (Centenary Lecture).

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Borough Polytechnic Chemical Society), at the Borough Polytechnic, Borough Road, London, S.E.1, at 7 p.m.—Prof. C. H. Bamford, F.R.S.: "Some New Developments in Polymerization".

## Thursday, February 25—Friday, February 26

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMATIC CONTROL GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1)—Symposium on "Gyros".

## Friday, February 26

BIOCHEMICAL SOCIETY (joint meeting with the Medical Research Society, at the London Hospital Medical College, London, E.1), at 9.40 a.m.—Scientific Papers followed by a Colloquium on "Structure and Clinical Significance of Immune Globulins".

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 2 p.m.—Geophysical Discussion on "The Magnetosphere".

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p.m.—Dr. A. Goldberg: "Reassessment of the Diseases of Porphyrin Metabolism".\*

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Logarithmic h.f. Aerials" opened by Mr. P. A. C. Morris, Mr. M. F. Radford, Mr. M. Telford and Mr. D. E. Watt-Carter.

ROYAL INSTITUTE (at 21 Albermarle Street, London, W.1), at 9 p.m.—Prof. R. L. F. Boyd: "The Lure of the Moon".

## Saturday, February 27

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. John F. Potter: "300 Million Years of London's Past".\*

## Monday, March 1

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY (in the Main Lecture Theatre, Department of Electrical Engineering, Exhibition Road, London, S.W.7), at 5.30 p.m.—Mr. L. Hix: "The Application of Automation to Railways".\*

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Control of Room Storage Heaters" opened by Mr. B. B. Rowson.

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. K. Stewartson: "The Boundary Layer".\*

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Professional Engineer and Man-Management" opened by Sir Wm. Carron.

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (joint meeting with the Microbiology Group, at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. A. K. Mills: "Research and Brewing" (Jubilee Memorial Lecture).

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Dr. Audrey Butt: "Peoples of the Forest and the Rivers".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (preferably with experience in the field of mammalian biochemistry) in BIOCHEMISTRY—The Registrar, Room (X), The University, Hull (February 24).

LECTURER or ASSISTANT LECTURER Grade B (graduate of a British university or with equivalent qualifications, and preferably some teaching experience) in MATHEMATICS—The Principal, Norwood Technical College, Knight's Hill, London, S.E.27 (February 27).

LECTURER or ASSISTANT LECTURER (with particular interests in palaeontology and stratigraphy, and research or other professional postgraduate experience) in GEOLOGY—The Staff Officer, College of Advanced Technology, Gosta Green, Birmingham 4, quoting ref. 395/2 (February 27).

RESEARCH ASSISTANT (graduate in medicine or biology and preferably experience in tissue culture) in the DEPARTMENT OF HISTOLOGY—The Registrar, The University, Liverpool, quoting Ref. CV/442/N (February 27).

ASSISTANT LECTURER and a COLLEGE LECTURER (with the degree of M.B. and Ph.D. or equivalent) in the DEPARTMENT OF PHYSIOLOGY—The Secretary and Bursar, University College, Dublin, Republic of Ireland (February 28).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS in BIOCHEMISTRY, CHEMISTRY, ENGINEERING, OCEANOGRAPHY or PHYSICS (experimental or theoretical)—The Deputy Secretary, The University, Southampton (February 28).

LECTURER or ASSISTANT LECTURER in MATHEMATICS—The Secretary, The University, Edinburgh (March 1).

SENIOR LECTURER in the DEPARTMENT OF PHILOSOPHY—The Registrar, The University, Leicester (March 6).

LECTURER or ASSISTANT LECTURER in the DEPARTMENT OF PURE MATHEMATICS—The Registrar, University College of Wales, Aberystwyth (March 8).

LECTURER with a good honours degree and/or a higher degree in sociology or a cognate discipline, and preferably a knowledge of survey techniques and statistics) in SOCIOLOGY in the DEPARTMENT OF EDUCATION—The Registrar, University College of North Wales, Bangor, North Wales (March 8).

LECTURER in ORGANIC CHEMISTRY—The Registrar, The University, Leicester (March 10).

**CHAIR OF MATHEMATICS (The M'Laurin Chair)**—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (March 15).

**LECTURER or ASSISTANT LECTURER in EXPERIMENTAL PSYCHOLOGY**—The Assistant Registrar (Establishment), University of Sussex, Stanmer House, Stanmer, Brighton, Sussex (March 19).

**SENIOR LECTURER or LECTURER in PHYSICAL and INORGANIC or ANALYTICAL CHEMISTRY** at the University of Natal, Durban—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, March 22).

**ASSISTANT LECTURER or DEMONSTRATOR in BOTANY**—The Secretary, Wye College (University of London), near Ashford, Kent (March 31).

**PROFESSOR of ZOOLOGY** at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, March 31).

**RESEARCH ASSISTANT** (graduate in botany or agricultural botany) in the DEPARTMENT of AGRICULTURE, to work on the micro-ecology of fungal infections of leaves—The Registrar, The University, Leeds, 2 (March 31).

**IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS** (preferably with the degree of Ph.D. or equivalent research experience and below the age of 30) in BIOCHEMISTRY, CHEMISTRY, CHEMOTHERAPY, ENGINEERING, METALLURGY, PHARMACOLOGY or PHYSICS—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 1).

**LECTURER or ASSISTANT LECTURER in the DEPARTMENT of PHYSICS**—The Registrar, The University, Leeds, 2 (April 1).

**ASSISTANT LECTURER or a LECTURER in ORGANIC CHEMISTRY**—The Registrar, University College of Swansea, Singleton Park, Swansea (April 5).

**LECTURER or ASSISTANT LECTURER in the DEPARTMENT of METALLURGY**—The Registrar, The University, Leeds, 2 (April 20).

**LECTURER** (preferably with biochemical interests) in INSECT PHYSIOLOGY in the DEPARTMENT of ZOOLOGY and APPLIED ENTOMOLOGY—The Professor's Secretary, Department of Zoology, Imperial College of Science and Technology, London, S.W.7 (April 30).

**ASSISTANT LECTURERS** (preferably with some experience in the field of natural products) in ORGANIC CHEMISTRY—The Clerk to the Council, School of Pharmacy, University of London, 29-39 Brunswick Square, London, W.C.1.

**ASSISTANT PROFESSOR in the DEPARTMENT of BACTERIOLOGY**, to teach both undergraduate and postgraduate students and to initiate and develop an active research programme in either a medical or a non-medical field—The Chairman, Department of Bacteriology, University of Alberta, Edmonton, Alberta, Canada.

**ASSISTANT PROFESSORS** (with a Ph.D. or equivalent, and preferably with research interests in biophysics, magnetic resonance, cosmic radiation, upper atmosphere physics, or theoretical physics) in the DEPARTMENT of PHYSICS—Prof. C. E. Chalice, Department of Physics, University of Alberta, Calgary, Alberta, Canada.

**GRADUATE RESEARCH ASSISTANT** at the Regional Rheumatism Research Centre to work with medical staff in a well-equipped laboratory—The Administrative Officer, Stoke Mandeville Hospital, Aylesbury, Bucks.

**MATHEMATICIAN/SCIENCE GRADUATE** (preferably with experience of programming and an interest in biology) for a research project to identify bacteria using computer techniques—The Director, Central Public Health Laboratory, Colindale Avenue, London, N.W.9.

**RESEARCH DEMONSTRATORS** (with a good degree in botany or horticulture) in the DEPARTMENT of HORTICULTURE, to assist with practical classes in horticulture or plant physiology and carry out research in one of those subjects—Prof. O. V. S. Heath, F.R.S., University of Reading Horticulture Research Laboratories, Shinfield Grange, Reading, Berkshire.

**RESEARCH FELLOW** (physicist or inorganic chemist with the degree of Ph.D. or several years relevant industrial experience) in the DEPARTMENT of PHYSICS, to join a group working on the electrical properties of aluminium nitride and related compounds—The Registrar, University College of North Wales, Bangor, North Wales.

**SENIOR BIOCHEMIST** (preferably with honours B.Sc. and several years experience in hospital laboratories) in the METABOLIC UNIT—The Assistant Secretary, University College Hospital, Gower Street, London, W.C.1.

**TEMPORARY LECTURER or TEMPORARY ASSISTANT LECTURER** (pure or applied mathematician) in the DEPARTMENT of MATHEMATICS (may be a permanent appointment later)—The Secretary, University College, Gower Street, London, W.C.1.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

**University of Cambridge.** Titles of Dissertations Approved for the Ph.D., M.Sc., and M.Litt. Degrees in the University of Cambridge during the Academic Year 1963-1964. Pp. 27. (Cambridge: Board of Research Studies, The University, 1964.) [3011]

**University of Oxford.** Report of the Committee appointed by the Hebdomadal Council to make Detailed Proposals for Carrying Out the Policy Contained in the Further Report on the Closer Integration of University Teaching and Research with the College System. Pp. 10. (Supplement No. 1 to the *University Gazette*, November 1964.) (Oxford: The University, 1964.) [3011]

**Planning.** Vol. 30, No. 483 (November, 1964): Firms and Their Exports. Pp. 279-318. (London: Political and Economic Planning, 1964.) 6s. [3011]

**Experiment in Higher Education.** By Sir John Fulton. (The Tavistock Lecture 1963, delivered at University College, London, 4th December 1963.) Pp. 16. (London: Tavistock Publications, 1964.) 3s. 6d. net. [3011]

**London County Council.** Public Health Department: Scientific Branch. Annual Report of the Scientific Adviser, 1963. Pp. 84+6 photographs. (London: London County Council, 1964.) [3011]

**Philosophical Transactions of the Royal Society of London.** Series A: Mathematical and Physical Sciences. No. 1076, Vol. 257 (19 November, 1964): The Thermodynamic Properties of Solid and Fluid Helium-3 and Helium-4 Above 3 K at High Densities. By J. S. Dugdale and J. P. Franck. Pp. 1-29. 10s. 6d.; 1.55 dollars. Series B: Biological Sciences. No. 743, Vol. 248 (26 November, 1964): The Foetal Membranes and Placenta of the African Elephant (*Loxodonta africana*). By Prof. E. C. Amoroso and Dr. J. S. Perry. The Structure and Development of the Reproductive Organs of the Female African Elephant. By Dr. J. S. Perry. Pp. 1-51+plates 1-19. 45s.; 6.75 dollars. No. 745, Vol. 248 (26 November, 1964): The Late-Glacial and Post-Glacial Escarpment near Brook, Kent. By M. P. Kerney, E. H. Brown and T. J. Chandler. With Appendixes by J. N. Carroek, Caniffa A.

Lambert, J. F. Levy and A. P. Millman. Pp. 135-304+plates 19-22. 32s. 4.80 dollars. (London: The Royal Society, 1964.) [301]  
Science and Technology Bill. Pp. ii+12. 1s. 6d. net. Machinery (Government Bill. Pp. ii+7. 1s. 3d. net. (London: H.M. Stationer Office, 1964.) [301]

### Other Countries

**Travaux et Mémoires du Bureau International des Poids et Mesures.** Tome 22, Fascicule 2: La Mesure des Fils Géodésiques au Bureau International des Poids et Mesures. Par A. Bonhoure. Pp. 61. (Paris: Gauthier Villars et Cie., 1964.) [301]

**Effective Use of the Science Citation Index:** a Programmed Text. Pp. 52 (Philadelphia: Institute for Scientific Information, 1964.) [301]

**The University of the State of New York—The State Education Department.** Educational Leaflet No. 16: Bird Art in Science—The Growth of Tradition. By R. L. Scheffel. Pp. vi+30. (Albany, N.Y.: New York State Museum and Science Service, Education Building, 1964.) 50 cents. [301]

**Institut for Atomenergi:** Kjeller Research Establishment. Kjeller Report No. 74: New Type of Safety Amplifiers for Reactors. By Eina Jakobsen. Pp. iii+7+5 figures (Kjeller, Norway: Institutt for Atomenergi Kjeller Research Establishment, 1964.) [301]

**International Pacific Salmon Fisheries Commission.** Bulletin No. 15: The Migration and Exploitation of Pink Salmon Runs in and adjacent to the Fraser River Convention Area in 1959. By E. H. Vernon, A. S. Hourston and G. A. Holland. Pp. 296. (New Westminster, B.C.: International Pacific Salmon Fisheries Commission, 1964.) [3011]

**Australia: Commonwealth Scientific and Industrial Research Organization CSIRO Sixteenth Annual Report, 1963-64.** Pp. 187. Annual Report of the Division of Dairy Research, 1963-64. Pp. 26. Annual Report of the Division of Forest Products, 1963-64. Pp. 65. Annual Report of the Chemical Research Laboratories, 1963-64. Pp. 123. Annual Report of the Division of Tribophysics, 1963-64. Pp. 17. Annual Report of the Fodder Conservation Section, 1963-64. Pp. 9. (Melbourne: Commonwealth Scientific and Industrial Research Organization, 1964.) [3011]

**World Meteorological Organization, and Anti-Locust Research Centre.** Technical Note No. 54: Meteorology and the Migration of Desert Locusts. Applications of Synoptic Meteorology in Locust Control. By R. C. Rainey. Pp. 115. (WMO-No. 138. TP. 64.) (Geneva: World Meteorological Organization; London: Anti-Locust Research Centre, 1964.) 25 Sw. francs; 42s. [3011]

**British Guiana: Geological Survey Department.** Report on the Geological Survey Department for the year 1961. Pp. 46. 1 dollar (W.I.). Bulletin No. 32: Bibliography of the Geology and Mining of British Guiana. By C. G. Dixon and H. K. George. Pp. iv+87. 2.40 dollars (W.I.). Bulletin No. 34: Bauxites and Laterites of British Guiana. By Dr. D. Blackley. Pp. 156 (21 plates). 6 dollars (W.I.). Bulletin No. 35: The Geology of the Bartica Assemblage. By Dr. R. T. Cannon. Pp. 83 (12 plates). 4.80 dollars (W.I.). (Georgetown, British Guiana: Geological Survey Department, 1964.) [3011]

**Commonwealth of Australia.** Department of National Development: Bureau of Mineral Resources, Geology and Geophysics. Geological Map of South Alligator River Area, Northern Territory. Geological Maps—1 Mile Geological Series. Sheet 68, Zone 4: Mount Hayward, Northern Territory. Sheet 69: Zone 4: Tipperary, Northern Territory. 1:250,000 Geological Series—Explanatory Notes. Sheet G/50-A, Australian National Grid: Glenburgh, W.A. Compiled by M. A. Condon. Pp. 22+map. Sheet SE/53-2, Australian National Grid: Tanumbirini, N.T. Compiled by A. G. L. Paine. Pp. 15+map. Sheet SE/53-8, Australian National Grid: Calvert Hills, N.T. Compiled by H. G. Roberts, J. M. Rhodes and K. R. Yates. Sheet E/53-12, Australian National Grid: Mount Drummond, N.T. Compiled by J. W. Smith and H. G. Roberts. Pp. 17+map. (Canberra: Bureau of Mineral Resources, Geology and Geophysics, 1963 and 1964.) [3011]

**International Council for Building Research, Studies and Documentation.** C.I.B. Report No. 3: A Master List of Properties for Building Materials and Products. (Prepared by C.I.B. Working Commission W.31.) Pp. 20. (Rotterdam: General Secretariat, C.I.B., P.O. Box 299, 1964.) [3011]

**South Australia.** Institute of Medical and Veterinary Science—25th Annual Report of the Council, July 1962—June 1963. Pp. 74. (Adelaide: Institute of Medical and Veterinary Science, 1964.) [3011]

**Bibliographien des Deutschen Wetterdienstes.** Nr. 15: Neuere Arbeiten zur örtlichen Wettervorhersage (1960-1963). Bearbeitet von Rudolf Anfol. Pp. 11. Mitteilungen des Deutschen Wetterdienstes. Nr. 51 (Band 5): Die Buchenmast in Schleswig-Holstein und ihre Abhängigkeit von der Witterung. Von Walter Hase. Pp. 52. 4.80 D.M. Nr. 52 (Band 5): Synoptisch-Statistische Untersuchungen. Pp. 44. (Offenbach a.M.: Selbstverlag des Deutschen Wetterdienstes, 1964.) [3011]

**University of California Publications on Zoology.** Vol. 75, No. 1: An Analysis of Color Changes and Social Behavior of *Tilapia Mossambica*. By E. H. Neil. Pp. 1-58 (5 plates). (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1964.) 1.25 dollars. [3011]

**Fiji: Department of Agriculture.** Bulletin No. 43: Annual Reports of Specialist Officers, 1961. Pp. iii+116. (Suva, Fiji: Government Press, 1962.) 4s. [3011]

**National Science Foundation, Washington.** From Egg to Man: Biological Studies of Cell Differentiation. Pp. 10. (NSF Newsfeature.) (Washington, D.C.: National Science Foundation, 1964.) [3011]

**New Zealand: Department of Scientific and Industrial Research.** Information Series, No. 42: DSIR Handbook, 1964. Compiled by the Information Service. Pp. 104. (Wellington: Government Printer, 1964.) [3011]

# UNICAM SP.800

spectrophotometer for routine  
U.V. analysis and complete  
**automation**

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible Spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as *the* outstanding U.V. spectrophotometer. Now, in addition, Unicam offer a set of automation accessories which provide facilities for:

**AUTOMATIC** interchange of up to 4 sample and 4 reference cells

**AUTOMATIC** re-cycling over any preselected wavelength range

**AUTOMATIC** recordings at predetermined time intervals.

*Please send for descriptive brochure*

*Save operator time, increase speed and efficiency with Unicam automation for:*

ENZYME REACTION RATES

LIQUID COLUMN CHROMATOGRAPHY

ALL ROUTINE ULTRAVIOLET AND  
VISIBLE SPECTROSCOPY

# AGAROSE

A neutral galactose polymer obtained from Agar by a unique method using reagents having no toxicity.

- \* Negligible electroendosmotic properties.
- \* High gel strength.
- \* Non-toxic.
- \* Minimum adsorption properties.

This product and many ENZYMES and RELATED BIOCHEMICALS of the highest possible integrity are produced entirely in our own laboratories.

*Send for descriptive brochure*

**SERAVAC LABORATORIES (PTY.) LTD.**

Moneyrow Green, Holyport,  
Maidenhead, Berks., England.

## Bacterial Colony Counter

- Suitable for pathogenic and non-pathogenic bacteria.
- Fast counting with all transistor circuit.
- 4 Inch magnifier for viewing colonies.
- Counting by either reflected or transmitted lighting.
- Designed for both left- and right-handed use.

Please write for further details to:

## NEW THINKING IN UNDERGRADUATE TEACHING

THE final report\* of the Committee appointed by the University Grants Committee in March 1961, under the chairmanship of Sir Edward Hale, "to make a comparative study of undergraduate teaching methods and practices current in the universities and colleges of Great Britain in the fields of arts and pure and applied science", starts from the assumption that the main object of an undergraduate course should be the development of a student's capacity to think for himself and to work on his own. Although it reaches comparatively few specific conclusions, and definite recommendations are equally sparse, its thorough and sensitive discussion of problems that are of increasing importance is an invaluable contribution to the task of ensuring that university expansion is realistic and efficient. It demonstrates the complexity of the whole series of problems, the danger of facile generalization, and the folly of allowing organizational or administrative convenience to override the personal and human issues.

An interim report on the use of vacations by students was presented in June 1963, in which the Committee found that for a large proportion of students the long vacation is, academically speaking, time largely wasted. That was duly noted by the Robbins Committee when it reported later that year. However, the Robbins Committee, while expressing the opinion that students should be expected to spend a substantial part of their vacations on work related to their fields of study and that grants should be assessed on the assumption that students will be occupied with their studies during ten months of the year—though not necessarily exclusively with academic work—was reluctant to recommend changes in the academic year. In particular, it was opposed to a general lengthening of first-degree courses to four years, and it should be noted that its emphasis on responsibility, on the part of the teacher and of the student, was placed in the context of its remarks on vacations.

The Hale Committee in its final report, however, is led by this loss of time in vacations to suggest that sessional and final examinations should take place in November and that the academic year should begin in January, largely because of the salutary effect which the change would have on the use of the long vacation and the effective lengthening and better utilization of the three-year courses taken by most undergraduates. The Committee presents strong arguments for such a change, but does not consider the possibilities which have been strongly urged by Prof. B. R. Williams and Mr. C. F. Carter of rearranging undergraduate teaching to permit six eight-week terms for two intakes a year. This change is advocated on the ground that it would allow the number of undergraduates to be increased by 30 per cent with only a 10 per cent increase in building: the capital cost of the expansion up to 1980–81 recommended in the Robbins Report would be reduced from about £1,420 million to about £600 million. While this is urged as essential on economic grounds, it is also pressed from the point of view

of the misuse of vacations noted by the Hale Committee, and the consequent slight reduction in the length of term in most universities is not dismissed without consideration.

The Hale Committee in its final report departs in other respects from some of the conclusions of the Robbins Report, but before considering these the general framework of the Report should be noted. The comments on the use of vacations and the changes recommended in the university year are to be found in a chapter on the structure of degree courses and the university year. This is followed by two chapters on problems of organization and the introduction of students to the university. Information collected on the use students make of their time, and on student opinion, is summarized in the next two chapters, and then the question of lectures and discussion periods is considered at length, followed by a chapter on practical classes and another on examinations. A chapter on equipment of teaching gives rather more weight than did the Robbins Committee to the importance of adequate university libraries and of effective instruction in the use of libraries, while a final chapter deals with university teaching as a matter for training and study.

All this is preceded by an introductory chapter in which some general considerations are set forth which reveal the whole spirit of the Report. The Hale Committee has been impressed by the interest in, and concern for, undergraduate teaching shown by those university teachers who gave evidence. The testimony of this Report to the extent to which university teachers are already accepting the formidable challenge of the present situation should be set against many facile reproaches. It is manifest that many university teachers do seek to teach their subjects in such a way that they not only serve as a basis of professional skill but also stimulate and broaden the mind. It is also salutary to be reminded that the challenge cannot be met successfully without reference to the content of courses as well as to the methods by which students are taught.

Here the Committee refers especially to the way in which first-degree courses tend to become overloaded with fact, as a consequence of the growth in the volume and complexity of knowledge. In consequence, the student is in danger of spending too much of his limited time memorizing facts, and has insufficient time at his disposal to master the principles underlying his subject and to develop his powers of thought. Since the Committee believes, as already indicated, that the most important purpose of a university education is to teach the student to think for himself, this is a serious danger, for which it suggests that the first remedy is to keep the nature and content of courses under constant review in order to eliminate all unessential or obsolete material. This is not simply a matter of detailed pruning; it may on occasion demand a re-examination of the whole approach to a subject in undergraduate courses.

Here is a point on which the Hale Committee parts company with the Robbins Committee, which was inclined to favour a further increase in postgraduate work, partly to reduce the content of specialized knowledge required in first-degree courses. On the contrary, the

\* University Grants Committee. Report of the Committee on University Teaching Methods. Pp. v+173. (London: H.M.S.O., 1964.) 10s. net.

Hale Committee deplores any tendency to design and teach undergraduate courses merely as a preliminary to work for a higher degree. It is convinced that the essential purpose of the first-degree course is to give the student a preparation for his professional life which does not depend for its value on the addition of a postgraduate course. An undergraduate course should not aim solely or even primarily to equip the student with knowledge; it should also, and even more important, teach him to think for himself and work on his own.

That conviction inspires the Hale Committee's assessments of the methods and practice of university teaching, and in the context of university expansion to-day they are unquestionably right. Any other course is only too likely to lead to a mass of dissatisfied, unemployed, even unemployable, graduates. Moreover, concentration on postgraduate teaching has dangers for the university teacher, who may well become subject-centred and not student-centred. In the increasing size of universities and with growing numbers of students drawn from homes and backgrounds with no tradition of learning, only the utmost determination and enlightened administration are likely to keep undergraduate teaching centred, as it should be, on the student.

This administrative problem is explored in the chapter on problems of organization, and here the Committee differs from Lord Bowden in rejecting the view that all the advantages are with large departments. Fully recognizing that a department which is weak in research is thereby weakened for teaching, it nevertheless sees some truth in the dictum that the efficiency of an organization tends to vary inversely with its size, particularly on the pastoral and administrative side rather than in teaching in the strict sense. The existence of these problems is recognized by the universities, and the difficulties may become more acute as university departments become larger, but, while the Report outlines some of the problems to be considered, it makes no concrete proposals itself other than commending the practice of most universities of assigning each student to one member of staff for advice on his studies as a whole. The Committee is particularly concerned about the incompatibility between full departmental autonomy and the satisfactory conduct of multi-subject courses, and suggests that this requires further consideration. A student who belongs fully to no department is liable to be under a serious disadvantage, and the member of staff to whom he is assigned needs special opportunities of meeting the student for serious discussion.

The student's introduction to university life is related to such problems, and here one is impressed by the sensitive insight of the Committee. It recognizes that first-year students do get rather more personal supervision than other students, but all their teaching, whether by lectures, classes or discussion groups, tends to be in larger groups than that of other students. Moreover, it is in the student's first year that the risk of failure is greatest, and although the causes of first-year failure are not always academic, the Committee considers that sometimes failure could be prevented by timely intervention by a member of the academic staff who knows that the student possesses his confidence.

The Committee stresses the importance of every first-year student having opportunities, which he does not have to make for himself, to discuss his problems with a member of staff who is not a stranger to him. Preferably the person to whom he is assigned for advice should also

be the same one he meets regularly in a discussion period to be effective, staff-student contacts must be about some shared activity, the teacher-learner relation being the best. Further, the Committee points out that it is in the first year that the student should break through from the mentality of the schoolboy to that of the university student, and this cannot be done by lectures alone, where reliance on authority may tend to perpetuate the immaturity which the student should be discarding.

This aspect is considered more fully in the chapter in which the Committee discusses specifically the functions of lectures and discussion periods and their use in the universities. The Committee does not accept without qualification the view of the Robbins Committee that formal lectures delivered to small audiences have little value. It argues that some lectures could, with advantage, be eliminated, and that a large audience may have a stimulating effect, but it does not think that the size of the university affects the need for highly specialized lectures. These, the Committee suggests, are a necessary concomitant of highly specialized courses and may be a valuable means of communicating a scholar's enthusiasm to his students, though the case for highly specialized lectures cannot be considered simply from the point of view of undergraduate needs. It directs attention to other points which call for consideration when the justification for lectures to small audiences is being assessed, and it emphasizes that if a higher proportion of undergraduates are to receive a broader education, a higher proportion of first graduates will probably also tend to demand specialized postgraduate courses, some of which must necessarily be given by lecturers to relatively small audiences.

The pros and cons of the lecture as a means of university teaching are very fairly set out, and before considering the use of discussion periods the Committee makes two important comments. First, now that most students are receiving grants from public funds, and have been selected to the exclusion of other candidates, neither university authorities nor grant-making authorities can be indifferent to whether a student is availing himself of the teaching given. If it is clearly reasonable that authority should know whether a student is attending lectures, it is also reasonable that students should be informed if a series of lectures is one at which their attendance is considered necessary. This is the Committee's second recommendation, and while there may be practical difficulties in keeping a reliable attendance register for a large audience, that is no reason for leaving students in doubt as to the importance attached to a particular series of lectures.

On the functions and use of discussion periods the Hale Report is again at issue with the Robbins Report, which regarded the tutorial system used at Oxford and Cambridge as too exacting for most students, too costly and too demanding on teaching resources: its introduction into other British universities, it is believed, would be both impracticable and undesirable. These conclusions are challenged by the Hale Committee, which once again maintains the importance of the individual student whose needs are met so successfully in the individual tutorial. It questions whether this is necessarily so costly as the Robbins Committee alleged, if it is used to reduce the time given to other forms of teaching and to make the student do more for himself. Even if the figures given for Oxford and Cambridge are accepted—on which the

Hale Committee has reservations—the balance might not be expensive and, apart from the fact that some universities are believed to have used tutorials similar to those used at Oxford without costs becoming out of line with the national average, it refers to the possibility of the use of graduate students in tutorials to reduce the heavy demand on College Fellows.

As to whether the tutorial is too exacting, the Hale Committee insists that the purpose of a tutorial is to be as exacting as possible, and every student needs a system which evokes from him the greatest intellectual effort of which he is capable and which stretches his ability to the utmost. It is the merit of the one-to-one tutorial that the teaching can be suited to the pupil's ability and that he can be taken at his own best pace. Nevertheless, the Committee thinks that, whereas the amount of teaching by discussion which can be given to a student is limited, the work required for each tutorial or seminar should be substantial. Rightly used, teaching by discussion is a way of making the student do for himself what is too often done for him, and if it is used in this way the Hale Committee thinks that it would not be unduly expensive or burdensome on staff.

The Report suggests that at a time of expansion a critical study of the role of practical classes is required, subject by subject. With regard to examinations, the Hale Report recognizes the experimental innovations which are being introduced or proposed in some university examinations, and it emphasizes that continued study and experiment are important for two reasons. Examinations should measure, so far as possible, not only the candidate's knowledge but also the qualities and habits of mind for which his degree should vouch. Their effect on the student's education should be beneficial and encourage good teaching.

The subject of teaching equipment is one which at the present time will arouse the keenest expectations and interest. The importance of the university library has already been mentioned; the Committee refers also to the importance of students buying books for themselves, but questions whether any practical increase in the allowance for book purchase in students' awards would suffice by itself to bring about the desired increase in books so as to reduce the undue dependence of students on oral teaching. On accommodation, many complaints were found concerning that available for teaching by tutorial or seminar, and while most university teachers consulted were satisfied with lecture rooms, there was considerable complaint about laboratories, particularly for biology and geography. Many were dissatisfied with the available secretarial and technical assistance.

Since the Brynmor-Jones Committee is now independently examining the potentialities of closed-circuit television and other audio-visual aids in teaching science, it is natural that the Hale Committee's observations on the use of such aids should be limited, and it merely summarizes the replies to the questions about the supply and use of such aids, including sound-recorded material, other than sound films. On the other hand, the possible use of programmed learning in universities is discussed in some detail. This form of teaching it regards as sound in principle and *prima facie* applicable to some forms of university work. The most promising field at present appears to be in application to introductory courses in subject-matter of a factual kind, but its value requires testing by trial and error. Moreover, the preparation of a programme is most exacting and time-consuming, and,

to be economic, the programme must be widely used. For this, inter-university co-operation with *ad hoc* finance would be necessary.

This comment is closely linked with what is said in the final chapter on university teaching as a matter for training and study. The Hale Committee believes that if the expansion recommended by the Robbins Committee is to be achieved, and the standard of university teaching maintained without excessive claims on national resources and on the limited pool of ability, ways must be found of making better use both of university buildings and equipment and of the time of university teachers. For this it suggests that operational research is necessary, and particularly a policy of well-directed experiment in university teaching organized on an inter-university basis. This would involve, for example, a standing committee, with a full-time secretary, to promote and steer a concerted programme of experiment; adequate finance for the additional costs, to be administered by this committee; and publication of the results in such a way as to reach all those for whose teaching the results might be significant. The Hale Committee also envisages this body becoming a centre of information in this field, as well as exercising advisory functions.

The Hale Committee has furnished a Report of great value, not least in its correction of some hasty and ill-informed criticism of the universities. It should not only give pause to some of those obsessed with the advantages of size but also stimulate an insight into the needs of students and of teachers. Certainly it should encourage the understanding between teacher and taught and the sense of responsibility which the Robbins Report desiderated and which is all too often overlooked in discussion. There may well be impatience in some quarters with the caution of the Hale Committee, but its wisdom and imagination deserve attention. If the standards of university education are to be maintained, and if Britain's need for trained man-power and woman-power is to be met in quality as well as in quantity—without gross waste of her limited resources either of finance, of materials or of man-power—the expansion of higher education must be geared closely to the further enquiries which the Hale Committee suggests and take due account of all the factors which are discussed with such vision as well as understanding.

## CARDIO-VASCULAR HISTORY

### Circulation of the Blood

Men and Ideas. Edited by Dr. Alfred P. Fishman and Prof. Dickinson W. Richards. Pp. xiv+859. (New York and London: Oxford University Press, 1964.) 144s. net.

THE two editors of this weighty volume, Alfred P. Fishman, director of the Cardiorespiratory Laboratory, Columbia University Division, Bellevue Hospital, New York, and Dickinson W. Richards, Lambert professor of medicine emeritus, Columbia University College of Physicians and Surgeons, New York, have produced an authoritative history of cardio-vascular physiology. The former writes on the cerebral circulation, the latter (with William F. Hamilton) on the output of the heart. Contributions on different aspects of the subject are given by other cardio-vascular experts, nine American, two English, one Belgian and one Swedish.

Prehistoric man realized that the heart was a vital organ, for it is indicated in many cave drawings as the aim of the hunter. The ancient Egyptians also knew this and the organ's relation to the whole body through the blood vessels. The Chinese studied the heart and the

pulse and its variations. The Greeks counted the pulse by a water-clock. Hippocrates regarded the heart as a source of bodily heat. Herophilus (c. 300 B.C.) showed that the brain) and not the heart, was the seat of intelligence and sensation; he distinguished arteries from veins but held that the former contained air. This mistake persisted until Galen (c. A.D. 131–200) showed that arteries contained blood. He taught that the heart had three chambers with a porous septum. Galen advanced knowledge in many respects, but his errors persisted for centuries through dogmatic teaching. Then, with the Renaissance, Leonardo da Vinci depicted the four-chambered heart, and Vesalius in his *De fabrica* described its anatomy accurately.

As early as the thirteenth century something was known of the lesser circulation through the lungs. Ibn Nafis, an Arabian physician (1210–88) of Damascus and Cairo, questioned Galen's views on the ebb and flow of the blood in the body to some extent. In a manuscript he stated that the interventricular septum is solid and that part of the blood is aerated in the lungs. In the sixteenth century that martyr of science, Michael Servetus (1511–53), described the pulmonary circulation, as did Realduo Columbus in 1558. Fabricius, Harvey's teacher, in 1603 described the valves in the veins. Then in 1628 William Harvey published *De motu cordis* showing that the whole of the blood circulates through the human body. From this can be dated the sciences of experimental physiology and experimental medicine generally and the basis of a scientific approach to cardio-vascular problems.

Many investigators entered through the door thus opened by Harvey. Aselli (1581–1626) discovered the lymphatic circulation, Pecquet the thoracic duct in 1647. Malpighi (1628–94) confirmed Harvey's belief that blood passed from the arteries to the veins by discovering the capillaries. Thomas Willis (1621–75) described the arterial circle at the base of the brain known by his name. Here it may be observed that it was not until 1908 that C. E. Beevor (1854–1908) gave a complete description of the arterial supply to all parts of the brain (*Phil. Trans. Roy. Soc.*). The Rev. Stephen Hales (1677–1761) recorded and measured the blood pressure and investigated the dynamics of the circulation. Morgagni (1682–1771) first described heart-block, elaborated at a later date as Stokes-Adams disease by Adams and Stokes. Effective pulse-watches, percussion, and auscultation by the stethoscope increased knowledge of the heart and circulation. The microscope and chemical advances led to the study of the constituents of the blood, histology of heart muscle and structure of arteries and veins. The blood-pressure was more accurately estimated by special instruments, as was the velocity of blood-flow by the Weber brothers in the nineteenth century. They also confirmed Volkmann's discovery that the vagus nerve had an inhibiting action on the heart, and its centre was localized in the medulla a few years later.

From the earlier history the book proceeds to more modern discoveries. Of these only some selected instances can be given here. In 1907 Keith and Flack demonstrated the sino-atrial node in the right auricle which initiates the heart impulse. Mackenzie's work with the polygraph correlated arterial and venous pulsation with the heart-beat and differentiated between trivial and serious irregularities of the heart rhythm. The researches of Einthoven led to the use by Thomas Lewis of the electrocardiograph for the clinical investigation of heart disease and its aid in diagnosis and prognosis. Before this, perfusion of the isolated heart had led to further knowledge. Starling and Lovatt Evans had investigated the metabolism of cardiac muscle, and the last-named also the hydrogen-ion concentration of the blood. One of the ablest chapters (Chapter 8) in the book is written by Sir George Pickering, Regius professor of medicine, University of Oxford, on systemic arterial hypertension, a subject to which he has devoted many years of research.

The bibliographies appended to each chapter are good and the book is well indexed. The numerous illustrations including portraits of the earlier and more recent investigators who have made cardio-vascular history, constitute another admirable feature of the volume.

## NEW LIGHT ON WILLIAM HARVEY

### The Anatomical Lectures of William Harvey

*Prelectiones Anatomie Universalis De Musculis*. Edited with an Introduction, Translation and Notes, by Dr Gweneth Whitteridge. Pp. lxiv + 504 + 7 plates. (Edinburgh and London: E. and S. Livingstone, Ltd., 1964. 147s.

THIS book is a very satisfying, interesting and educative presentation of William Harvey's anatomical lectures and of the problems they present.

It should be known that they were delivered at the Royal College of Physicians during 1616–28. In 1582 Lord Lumley had established in perpetuity a lectureship in surgery which was to present "in good order all the whole course of the Art and Science of Surgery". In addition, the Lumleian Lecturer was enjoined to hold a public anatomy in the winter of each year. Harvey was appointed in 1615. His notes that survive are contained in two manuscripts in the Sloane Collection in the British Museum. One manuscript has been published before the other, *De musculis*, is printed for the first time.

The original notes are in Latin with many abbreviations. Harvey added later notes and comments and phrases in English. The work of transcription, of translation and of presentation is obviously difficult and complex. Dr Whitteridge prints her transcription on the left-hand page and her translation on the right-hand one. The translation is rendered as running prose.

It is impossible to review this book without comparing it with the only other attempt at translation, published in 1961 by Drs. O'Malley, Poynter and Russell. Their book gives their translation but not their transcription, and the translation is in a disjointed form and so does not make pleasant or easy reading. Dr. Whitteridge's presentation is much more readable and the printing and arrangement are more attractive.

An assessment of the comparative merits of the scholarship of the two books is difficult and could only be achieved with certainty by reference back to the original text. It can be said that the impression gained is that Dr. Whitteridge's transcription is the more reliable. Certainly it makes easier sense. Thus O'Malley's translation states: "In quantity the heart of man is large, wherefore timid, wherefore courage from a common intelligence". Whitteridge renders the same passage: "The heart is large in men, and for this reason they are timid by nature and their courage comes from their intelligence".

In the description of the testes Whitteridge renders "The testes are so-called because they attest virility Worthy to be made a Pope". The Latin text she gives is "*Dignus Papari*", and her notes state that in order to avoid any repetition of the scandal of election of "Pope Joan" the cardinals ordained that the sex of the candidates should be determined by examination of the genitalia. It is somewhat startling to find in O'Malley's version "The testes which attest virility, worthy to be eaten"!

In addition to the translation of the lectures there is an excellent introduction of some sixty pages that is interesting and valuable in presenting many Harveian facts, notably a section on the state of Harvey's ideas on the circulation of the blood as expressed in these lectures. The argument is convincing that at the time they were delivered Harvey's ideas were far from fully formed and had not been crystallized by his later experiments. The notes that have been taken to indicate he understood the

true nature of the circulation are shown probably to have been added later, about 1627 or 1628. This section will repay careful study. Dr. Whitteridge points out that it is not the similarities with *De motu cordis* which are of importance in determining the state of Harvey's knowledge in 1616 but the dissimilarities.

Another interesting section deals with Harvey's interest in surgery and pathology. It presents clearly the relationship between physician and surgeon at that time and how the instruction of surgeons rested with the physicians. She completely rejects the statement by O'Malley, Poynter and Russell that Harvey practised surgery himself and had actually performed lithotomy.

The final paragraph of the introduction states "these lecture notes show Harvey primarily as an observer rather than as an experimentalist. . . . The rigorous discipline of argument and experiment of the *De motu cordis* was yet to come. That work was to be seen later as one of the first examples of modern scientific method. By comparison the lectures are backward looking. From Antiquity, through the Middle Ages and the Renaissance, medical education is unbroken in its tradition and in this tradition the lectures are enshrined. They do not reach beyond it to the dawning of the scientific attitude of the second half of the seventeenth century".

The book is handsomely and finely produced in a manner fitting for such a scholarly, impressive and instructive presentation of Harvey's lectures. It deserves great praise and is very strongly recommended.

RUSSELL BROCK

## PATHO-PHYSIOLOGICAL PHARMACOLOGY

Kurzes Lehrbuch der Pharmakologie

Von Prof. G. Kuschinsky und Prof. H. Lüllmann. Pp. viii + 332. (Stuttgart: Georg Thieme Verlag, 1964.) 33 D.M.

THIS text-book attempts to present pharmacology and those parts of toxicology which are relevant to clinical medicine on the basis of patho-physiological considerations, stressing structure-activity relationships. By describing the actions of drugs as they affect physiochemical processes, in addition to giving an account of their effects on the organs of the body, pharmacological observations are evaluated in their relationship to biochemical and biophysical data. Considered from this angle, pharmacology is seen to deepen the understanding of processes as they occur in health and disease, in contrast to the notion that it consists merely in a description of a vast variety of drug effects on various parts of the body.

The references are mainly confined to review articles which would guide the reader to the original papers. Unfortunately, quite a few of the reviews quoted are ten or more years old. On the other hand, the authors have in many cases succeeded in integrating recent findings and modern theories into the presentation of their subject. For example, on the basis of the hypothesis of the storage mechanism of biogenic amines in the tissues, a brief and concise explanation is offered of the apparently contradictory influence of cocaine on the action of catecholamines, which is intensified, and on the effect of epinephrine and tyramine, which is diminished (p. 24). Tracings are well chosen and structural formulae of many compounds and their generic and trade names are included. Practical implications of the pharmacological actions, clinical usage and doses are indicated. Thus the chapter dealing with the pharmacology of smooth muscle ends with an appendix which outlines the treatment of bronchial asthma, hypertension and migraine. Although these surveys are necessarily kept very short, phaeochromocytoma and unilateral

kidney disease should have been included as curable types of hypertension.

Sections which have received a thorough and up-to-date treatment include those dealing with the pharmacology of the autonomic nervous system and the kidney. Other parts are less comprehensive or frankly deficient. Some of them may be mentioned here: The clinician or student will scarcely be able to grasp the meaning of the brief paragraph which states that for a given stage of anaesthesia thermodynamic activity is approximately the same for the various anaesthetics, while solubility coefficients, oil-water distribution coefficients and partial pressures of the gases in the respiratory air show marked differences. The attitude to the use of amidopyrine is that common in parts of the European Continent and contrasts sharply with the fear of agranulocytosis that limits its use in other countries. The description of insulin does not include the principles involved in the preparation of the different kinds, nor does it mention that the lente type should not be mixed with other preparations and the reason for it. Treatment of diabetic coma by 50-100 units insulin intravenously and by subcutaneous injection, in addition to glucose, water and electrolytes, is surely inadequate. Though the significance of glucose-6-phosphate-dehydrogenase deficiency for idiosyncrasy to certain drugs and for the development of some haemolytic anaemias is stressed, the genetically determined differences in sensitivity to suxamethonium are not discussed. The actions of ACTH are only considered very briefly and its effect on cholesterol and ascorbic acid levels is not explained; its therapeutic uses are not sufficiently described, while half a page is allotted to thyrotropic hormone. In the section dealing with chemotherapeutic agents and antibiotics nitrofurantoin should have been included, and paramomycin and perhaps the ampicillin treatment of typhoid mentioned.

The index is well compiled and includes the names of many preparations. In spite of the uneven treatment of the different chapters, the book is an up-to-date source of pharmacological knowledge and deserves a place on the shelf of medical practitioners and students.

L. WISLICKI

## INFORMAL AND INFORMATIVE ASTRONOMY

The Universe

Karl Taylor Compton Lectures. By Otto Struve. Pp. ix + 159 (figures). (Cambridge, Mass: The M.I.T. Press (Massachusetts Institute of Technology), 1962.) 44s.; 4.95 dollars.

THROUGH his numerous articles in *Sky and Telescope* Prof. Otto Struve has created a distinctly personal style of semi-popular writing in astronomy. These articles were intended to give to the informed public whatever happened to be the latest among professional astronomers. Physical ideas were set forth with lucidity, accompanied by ample arithmetical illustrations, but the mathematics was never allowed to go beyond an odd square root here and there. The style, though informal, was by no means facile, because of an almost visible desire to be informative on the part of the author. Ideas succeeded one another with little regard for linguistic fluency, but this very shortcoming, like the occasional stammer of a great speech maker, enhanced rather than diminished the power of persuasion. This informal and informative style found its full expression in the 1959 Karl Taylor Compton Lectures, now available in book form.

Of the six lectures, that on binary stars is outstanding. Such an illuminating account could only have come from someone who had a deep sense of personal involvement

in the subject. Prof. Struve's own contribution in this field was not mentioned; the limelight was on the discovery of the binary nature of Nova Herculis, and what it implied in our search for the missing link in stellar evolution. The other lectures were on stellar evolution, origin of the Solar System, galaxies and radio astronomy. In all these Prof. Struve can be depended on for being up to date (in 1959)—and this means the lecture on radio astronomy is already somewhat out of date. The last lecture is an odd-man-out. It has for its title "Man and the Universe", but turns out to be a plea for carrying out more astronomy; the reasons, apparently, are (1) the Russians had fired the first satellite; (2) astronomy had been useful to physics; (3) there may be other intelligent beings outside our planet.

There is a large number of diagrams and photographs in the book—too many photographs, I feel. A large assortment of lantern slides, each shown for a brief moment, may be just the thing in public lectures, but to reproduce them all in print, which seems to be the case, is sheer extravagance. The diagrams are all right because they serve a particular purpose, but the photographs, most of them familiar anyway, simply take up a lot of space and put up the cost of the book out of proportion to their usefulness.

T. KIANG

## SPACE SCIENCE

### Interplanetary Dynamical Processes

(Interscience Monographs and Texts in Physics and Astronomy, Vol. 8.) By E. N. Parker. Pp. viii+272. (New York and London: Interscience Publishers, a division of John Wiley and Sons, 1963.) 95s.

### Astrophysique

(Cours à l'usage de la Licence.) Par E. Schatzman. Pp. 150. (Paris: Masson et Cie, 1963.) 29 F.

### Radio Astronomy

By J. Steinberg and J. Lequeux. Translated by R. N. Bracewell. Pp. xii+260. (New York: McGraw-Hill Book Company, Inc.; London: McGraw-Hill Publishing Company, Ltd., 1963.) 77s.

*INTERPLANETARY Dynamical Processes* is devoted to a discussion of the theory of coronal expansion or the theory of the 'solar wind'. This is a question which has acquired great importance since the first introduction of this subject more than ten years ago. The problem is introduced and the observational evidence presented and discussed in the first three chapters. The next six chapters are concerned with establishing the mathematical techniques used, that is, the necessary hydrodynamical equations and their solutions under various conditions. The part played by magnetic fields, irregularities and the propagation of high-energy particles in the expanding corona are discussed. The book is concluded by a discussion of the question of coronal expansion for stars other than the Sun.

This is a particularly interesting account of the theory of coronal expansion. It summarizes in one volume the hydrodynamical theory of such expansion and presents the arguments and evidence in support of this method of approach. The accounts of the work were previously scattered in the literature. While expensive, the price is not unduly high for a specialized monograph which must have appeal limited to the fields of solar and space dynamics.

*Astrophysique (Cours à l'usage de la Licence)* begins by discussing the means of obtaining astrophysical information before discussing the Sun, double stars, variable stars, stellar distributions and motions, interstellar material and extragalactic nebulae. The subject is covered in a very concise way. The compactness is of such a

degree that it would be difficult to use this text independently either of the course of lectures on which it is based or a set of reference texts.

However, there is a need for this type of text where there is more demand for astrophysics courses. The book allows rapid refreshment of the memory and allows the student to obtain a grasp of the subject as a whole. In this respect, however, the price of the book is somewhat high. It would be desirable to see more of this type of document associated with courses given in Britain. While the expense of the book precludes its use by students, it should find a place in astronomical libraries, where it can be used to good effect in the planning and presentation of new courses.

The translation of J. Steinberg and J. Lequeux's book brings a fine text to the English-speaking readership. The standard at which *Radio Astronomy* is written will make it an excellent text to supplement a course of lectures on radio astronomy at degree level. The topics covered are: the role of the atmosphere; thermal radiation; simple radio telescopes; interferometers and aperture synthesis; spectral observations; mechanism of the emission of radio waves; radio emission from the Sun; radio emission from the Solar System; galactic radio emission; galactic radio sources; extragalactic radio sources. The treatment is kept simple, but no endeavour is made to avoid mathematical treatment at the expense of clarity. The section on the mechanism of radio emission is of particular interest.

While useful as a text-book, its value should not end there. It is perfectly comprehensible to advanced general readers who wish to gain some insight into the techniques and the results of radio astronomy. There are few books of this level on radio astronomy and it is indeed welcome that this excellent French text should have been translated by such a well-known radio astronomer as Dr. R. N. Bracewell.

D. McNALLY

## PRESENT STATE OF HISTONE STUDIES

### The Nucleohistones

Edited by Prof. James Bonner and Dr. Paul Ts'o. Pp. xvii+398. (San Francisco and London: Holden-Day, Inc., 1964.) 12.75 dollars.

THIS book is the outcome of the first World Conference on Histone Biology and Chemistry in April 1963. It is worth stating at the outset that this is a very useful work as it contains most of the present data on histones and, unlike many *Proceedings* of international meetings, is likely to be consulted for some time to come.

It is inevitable in a work of this nature that there will be considerable overlapping of the individual contributions, and the student wishing to ascertain the present-day views on histone function will need to work carefully through with a notebook and then cross-reference his own notes. This is not a criticism of the work of the editors who have tidied the contributions into sections which are, to some extent, self-contained. They have also avoided verbatim reports of discussions, which can be merely distracting to the reader who does not know the participants. The difficulty in assessing the present standing of histones reflects the diversity of opinions expressed in the book, all founded on well-documented experiments; it is probably a salutary introduction for any student entering the field of molecular biology.

The book opens with a very readable chapter on the history of histone chemistry, starting with the work of Hoppe-Seyler and ending with the Kossel school. This is followed by ten chapters by various authors, dealing with details of histone chemistry. The heterogeneity of

histones from a single source, the characteristics of histones from different sources, techniques and results of analyses, are fully discussed, making this a useful reference section. The rapid development of this topic is, incidentally, made obvious by the confusion of nomenclature and the plea for a unified system.

The structure of nucleohistones opens with a chapter by Zubay in which he discusses in detail the essential feature of the problem, the function of histones. After a review of the previously published evidence and an exposition of the Jacob-Monod theory of the regulation of protein synthesis, he concludes that most histones are involved solely as structural proteins concerned with the supercoiling of DNA and its availability as a source of information during interphase. It is clear from subsequent papers that, although much has been discovered about the properties of isolated histones, for example the  $\alpha$ -helix content, the nature of their interactions with DNA is relatively unknown.

The remainder of the book is largely concerned with dynamic aspects. In the chapters concerned with histone metabolism results of turnover investigations lead several authors, for example Dounce *et al.* and Busch *et al.*, to the conclusion that specificity requirements for gene inhibition cannot be met by the histones. In the following section on enzymology the control function of the histones is further discussed. Huang and Bonner, and Allfrey and Mirsky, report experiments showing that histones inhibit DNA-primed RNA synthesis, thus providing experimental evidence for the Stedmans' inhibition hypothesis, while Billen and Hnilica have shown some specificity of inhibition of DNA synthesis *in vitro* by different histone fractions.

The role of histones in development covers examples of function in one cell cycle and aspects of differentiation. The problem of specificity is raised again by Bloch, as a consequence of his conclusion that probably any histone could combine with any DNA, and by Zalokar, who considers that removal of histone from incompetent genes does not make the genes active but makes them susceptible to the action of inducers.

The last section of the book is entitled "Thoughts for the Future", and in five chapters the various authors speculate on the developments as they see them. This will be to many readers the most thought-provoking section. In a final chapter the editors set out in a logical sequence the various possibilities for histone behaviour within the cell and discuss specific experiments designed to test them. This forms an elegant essay demonstrating the way in which to decide on the information required from an experiment and how to approach the interpretation of results.

The reader will have realized that this review does not do justice to all the authors. By mentioning the points raised by a few of them an attempt has been made to illustrate the coverage of the work. It will be apparent that although a great deal is known this has mainly resulted in a realization that the structure and functions of histones is a more complicated problem than was thought a decade ago.

A. R. CRATHORN

## KARL POPPER'S CRITICAL RATIONALISM

The Critical Approach to Science and Philosophy  
Edited by Prof. Mario Bunge. (Essays in Honor of Karl R. Popper.) Pp. xv + 480. (New York: The Free Press of Glencoe, a Division of the Macmillan Company; London: Collier-Macmillan, Ltd., 1964.) n.p.

KARL POPPER is a philosopher who, during a period of philosophical disillusionment—a "time of drought", as Karl Löwith has called it—has had the

courage to put forward a comprehensive view that has relevance for most of the branches of philosophy as well as for mathematics and the natural sciences and for history and the social sciences. His view was first presented in *Die Logik der Forschung* in 1934, where he argued that scientific theories are not established inductively but must be regarded as hypotheses—he later used the term "conjectures"—which hold the field so long as they have not been shown to be false when put to the test.

Theories are not established or verified, but withstand or fail to withstand attempts to refute them, so that the path to truth is through the rejection of error. In subsequent writings, notably in the *Poverty of Historicism*, which appeared in *Economica* in 1944, and in *The Open Society and its Enemies* published in 1945, Popper developed his non-inductivist, non-verificationist view into a general defence of rational criticism in opposition to the methods of dogmatism and authority. He argued that in morals the prevention or lessening of suffering takes precedence over the production of happiness, and gave reasons for preferring piecemeal reform to total planning. Like Comte, Popper holds that science and morality are closely interlocked though not identical, but, unlike Comte, he holds that large-scale prediction of the future of society is in principle impossible.

This collection of essays in his honour is divided into four parts. Part 1 contains eight essays under the general heading of "The Critical Approach to Philosophy". Of these we may specially notice the first, in which W. W. Bartley III argues that Popper's critical method implies the inadmissibility of any attempt to 'justify' a theory, or, I suppose, a belief, practice or institution. For justification, according to Bartley, requires an appeal to some ultimate authority, whereas criticism, with its reliance on falsification, needs no such extraneous support. Paul Bernays, in a paper entitled "Reflections on Karl Popper's Epistemology", while in agreement with Popper's main tendency, suggests that testing is not such a pessimistic thing as Popper assumes when he takes it as the attempt to overthrow the conjecture being tested. Bernays's critical examination of testing and of criticism itself is brief but fruitful. Part 2 contains four essays under the general heading of "The Critical Approach to Logic and Mathematics". We may here note W. C. Kneale's defence, against Popper, of the view that the necessity of laws of Nature is similar in kind to the necessity of laws of logic. There are other papers on logic by H. B. Curry, N. Rescher and G. Stahl. Part 3, entitled "The Critical Approach to Science", contains twelve papers. Feigl criticizes instrumentalism and incidentally discusses the quantum theory, as does O. R. Frisch in a paper on that subject. A. Grünbaum, in a paper on irreversibility, criticizes Popper's view, stated in *Nature* in 1956, 1957 and 1958, that the 'arrow of time' is not closely connected with and not dependent on the law of entropy. Popper's and Kneale's views on natural necessity are briefly discussed at the end of Yourgrau's paper on the reality of elementary particles. The fourth part of the book is called "The Critical Approach to Society and History", and of the five essays that make it up we may mention Pieter Geyl's appreciative review of Popper's *Open Society*. The book concludes with a bibliography of Popper's writings.

There is, of course, plenty of support for Popper in this volume, but it is far from being a collection of laudatory testimonials. In some of the papers he is not discussed at all, and in others, as we have seen, he is honoured by being criticized. He is also honoured by the galaxy of talent who have contributed to the book, for it is a tribute to the interest that his views have aroused, as well as to the skill of the editor, that space only allows me to mention contributions by Gombrich and by Hayek and forces me to leave many others unmentioned altogether.

H. B. ACTON

### The Oxford Book of Birds

By B. Campbell and D. Watson. Pp. xvi+207 (illustrations). (London: Oxford University Press, 1964.) 35s.

AMONG the many current books on British birds, this may be acclaimed the best at its particular level, between the pocket guide to identification and the advanced text-book. It is indeed excellent for identification purposes, but it also gives a satisfying amount of solid information on distribution, habitat and behaviour. Each of the 96 colour plates depicts several species, and two or more examples where there are important differences in plumage according to sex, age or season. All species that have occurred in the British Isles are figured except a few rare vagrants, and even some of these and of introduced species that have become locally naturalized. Mr. Watson is skilful with his brush and obviously knows most of his subjects in life. These are shown in a 'natural' setting; although this raises occasional difficulties of scale and involves some incongruities of juxtaposition, it has the advantage of immediately relating the bird to its habitat and at the same time produces a pleasing picture. The standard of colour reproduction is high, although in certain instances some predominant tint appears to be too strong.

The text is thoroughly reliable and up to date. It is conveniently arranged with from one to three paragraphs about each species on the page facing its illustration. Dr. Campbell has succeeded in compressing a great deal of information into limited space, by careful selection and by using an economical style; the result is pleasantly readable. He has also avoided overloading the text with information that is irrelevant to the British status of the species, such as the breeding habits of those that are not natives. For the commoner birds the treatment ends with an ingenious single-line calendar—a series of numbers, with typographic variations, that shows at a glance in which months the species is (a) present, (b) nesting, and (c) in song.

At the beginning and end of the book there are useful brief chapters on general subjects such as classification, anatomy, flight, behaviour and breeding, migration and numbers. Black-and-white drawings illustrate these and also show the appearance of various waders and ducks on the wing.

LANDSBOROUGH THOMSON

### Intersexuality in Vertebrates Including Man

Edited by C. N. Armstrong and A. J. Marshall. Pp. xi+479. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1964.) 90s. net.

THE scope of this excellent text-book is logical but unusual, in combining a series of review articles directed chiefly to zoologists, with two outstanding clinical reviews. In the context of biology it is eminently reasonable to discuss intersexuality in vertebrates by phyla, ending with a special discussion of it in man; it is none the less a relatively new gesture by publishers in the direction of an interdisciplinary human biology; this approach is so useful that one must hope that the clinical sections are not overlooked by medical readers, coming as they do after a sizable body of zoology.

Intersexual phenomena, normal and pathological, are a good deal commoner in vertebrates than had been realized until recently—the number of known examples of hermaphroditism in fish, for example, has been growing steadily since the beginning of the present century. The bulk of this book is taken up with a series of good specialist reviews—of fishes (J. W. Atz), amphibia (C. L. Foote), reptiles (T. R. Forbes), birds (E. Taber) and non-human mammals (J. Bruner-Lorand), prefaced by a full discussion of vertebrate chromosome deviations by R. A. Beatty, excluding those in man. There is also an informative and entertaining editorial foreword by A. J. Marshall. Human intersexuality is then dealt with in full clinical detail,

together with the present state of knowledge about human chromosome anomalies, by C. N. Armstrong. This article is well illustrated with case photographs and histories, and preceded by a series of paragraphs on the legal and logical definitions of maleness or femaleness. Both as a summary of sex-determination in man, and as a short primer of an obscure but important clinical problem in differential diagnosis, this would be hard to better. Especially welcome, however, is the good judgment of the editors in following this essay with another, by M. Roth and J. B. Ball, on the behavioural types of intersexuality in man (homosexuality, trans-sexualism, transvestism) depending on the mis-learning of a gender role, which should serve once and for all to end the confusion between these states and that of physical intersexuality. An incidental but important use of the reviews of phyla is that they provide most valuable data for the selection of experimental animals. Bibliographies are adequate without being inflated, illustrations are good, and the style of the whole is readable. The book is a most useful addition to the library of any department or worker concerned with cytology, zoology, veterinary surgery, or clinical medicine—or with the teaching of these at pre- and post-graduate levels. ALEX COMFORT

### The Natural Radiation Environment

Edited by Prof. John A. S. Adams and Wayne M. Lowder. Pp. xiv+1069. (Chicago and London: University of Chicago Press, 1964. Published for William Marsh Rice University.) 105s.

THE proceedings of scientific conferences or symposia are not usually the best material for a text-book, since there is no reasoned account of the fundamental parts of the subject and the papers tend to be heterogeneous in outlook. International symposia tend to suffer from a further disadvantage: presentation of a paper is frequently the passport to the meeting, with the result that many relatively poor papers are written. It is only the major workers in the field, and as a rule the contributors from abroad, who can be relied on for really good papers, the latter primarily because the expense of sending them must be justified by a significant contribution to the conference. This is evident in *The Natural Radiation Environment*, where the average standard of the American papers is well below that of the European contributions. The main criticism that can be levelled at some of the authors is that their topics are parochial in the extreme and make little contribution to the overall knowledge of the subject. The book as a whole—and presumably, therefore, the symposium—suffers from too wide a diversity of interest and it is occasionally difficult to see how a paper fits into the general scheme.

The subject-matter is divided into two main sections: the first, entitled "Environmental Radiation Sources", includes radioactivity in the earth, in water and in the atmosphere,  $\alpha$ -radioactivity (on which one of the best papers has been written) and cosmic radiation. The second part, "Environmental Radiation Measurements", includes instrumentation and techniques, aerial surveys and ground measurements and surveys. Apart from one or two notable exceptions, the second part probably contributes more to our knowledge of the subject than does the first.

A short section is devoted to an intercalibration experiment carried out on the day before the symposium. In this, six different instruments, five from the United States and one from Great Britain, were used in three environments of widely differing natural radiation-levels. The results are interesting, but more could be made of them.

This is certainly not a general text-book on environmental radiation. It has perhaps much for the specialist, but its diversity and its price will fail to attract a wide audience.

H. D. EVANS

## NEW HIGH ANNUAL AWARDS IN AUSTRALIA

By OSCAR A. GUTH

School of Physics, University of Sydney

FIVE new Australian annual national awards—in science, medicine, literature, education and art—were presented in Canberra for the first time on January 21. The awards are among the richest in the world, each consisting of a gold medal and citation and £A5,000 (tax free). Named the Britannica Australia Awards after their sponsors, Encyclopaedia Britannica Inc., Chicago, the awards are administered and adjudicated by an entirely independent body in Australia, comprising some thirty-six of Australia's leading experts in the five award fields.

The Britannica Australia Awards are intended as a stimulus to science and culture in Australia and to reduce the country's 'brain drain'. They are made for work of outstanding merit in the respective award fields involving an original contribution or development and having a direct connexion with, or benefit for, Australian life. The awards are open to Australian nationals whether living at home or abroad, or non-Australian nationals who were living in Australia at the material time.

The first five awards—for 1964—were presented during an impressive ceremony in the Council Room of the Australian National University by the University's vice-chancellor, Sir Leonard Huxley, who is chairman of the Britannica Australia Awards General Council. The choice of the first six winners—the medical award was made jointly to two recipients—provides a good illustration of the character of the new awards.

The 1964 award for natural and applied sciences went to Dr. J. Griffiths Davies, who is chief of the Division of Tropical Pastures, Commonwealth Scientific and Industrial Research Organization (Australia). Dr. Davies established the Division of Tropical Pastures in Brisbane, Queensland, in 1952 to meet the challenge of a programme of pasture research leading to the establishment of satisfactory pastures in tropical areas. Suitable pasture plants, particularly legumes, were sought and found, and his Division has acquired a high reputation at home and abroad for its theory and practice of pasture science in the tropics.

The medicine award for 1964 was shared by Sir Norman Gregg, of Sydney, and by Dr. Kate Isobel Campbell, of Melbourne. Sir Norman, in 1940, in the course of his work as an ophthalmologist, recognized that congenital cataract was seen in a quite unusually large number of infants. He discovered that this serious condition was occurring only in children of mothers who had suffered an attack of German measles (rubella) during the early months of pregnancy. His completely unexpected finding in 1940 has led to the opening up of an important new field in medical science—the pathology of the unborn child. More directly it was followed in Australia and elsewhere by detailed investigations of the effect of rubella in pregnancy, which showed that, in addition to cataract and blindness, the virus could give rise to deafness, malformation of the heart and other less clearly definable conditions.

Dr. Kate Campbell, an acknowledged authority on disease in the first months of life, was the first in the world, in 1951, to show that an important cause of blindness in premature babies, retrolental fibroplasia, was due to over-treatment with oxygen. During her research she found that nurseries which used more elaborate apparatus to maintain a constant high level of oxygen had a much higher incidence of eye trouble than occurred in institutions where oxygen was given with simple or makeshift

apparatus, and at lower concentration. Dr. Campbell realized then that benefit to the blood must be balanced against possible harm to the eyes, and her analysis of the situation has since saved many children from blindness.

The literature award for 1964 went to Miss Judith Wright, who over the past twenty years has made a wide-ranging and permanent contribution to Australian literature. Best known as a lyrical and meditative poet of great technical mastery, she has also published outstanding short stories, a chronicle of family life based on her own pioneering ancestors, children's books and a considerable amount of literary criticism. The citation of her award particularly refers to her book *Five Senses* published during the past year.

The education award for 1964 went to Dr. Harold S. Wyndham, director-general of the State Department of Education in New South Wales since 1952. Dr. Wyndham received the award mainly for his leadership of a committee the investigations and final report of which led to major changes and reforms in the New South Wales secondary school curriculum. One of the main features in the new "Wyndham Plan" education—as it has become known in Australia since its implementation in 1962—is that it requires all high-school students to study an integrated course of science during the first four years of their six-year secondary education. This four year science course breaks new ground in its insistence on the teaching of physics, chemistry, biology and geology as one integrated subject and on the inculcation of the student to learn to think and understand science and scientific method as a whole rather than being presented with science in 'bits'. Dr. Wyndham's citation said that his new pattern of education had not been limited in its effect to his home State, but that it was also being closely studied throughout Australia, as well as abroad, and would serve as a test for other systems. Dr. Wyndham therefore stood out as a leader in the field of modern Australian secondary education.

The 1964 art award went to the already famous Australian painter and portraitist, William Dobell. Mr. Dobell, now sixty-five years old, returned to Australia from London in 1939, and by his steadfast example and his quiet insistence on the professional status of the painter, has significantly helped to establish the Australian artist as an integral part of the country's community. His citation said that his paintings and his name were now indelibly woven into the fabric of Australian life.

The first presentation ceremony of the Britannica Australia Awards at the Australian National University was marked by messages of goodwill from both the Governor-General of Australia, Lord De L'Isle, and the Prime Minister, Sir Robert Menzies. The chairman, Sir Leonard Huxley, said in his address that the awards would give great encouragement to creative work in the arts and sciences in Australia. He recalled that this new award scheme, second in richness and prestige only to the Nobel Prize, had been announced only a short six months previously, and he commented on the remarkable speed with which the scheme had been launched and put into operation, "reflecting great credit on the members of the award committees who, recognizing the great national importance of this scheme and serving in an entirely honorary capacity, have given freely of their time and experience to ensure its success". Sir Leonard also directed his thanks to the sponsoring Company whose

vice-president, Mr. L. J. Maher, had flown to Canberra from Chicago for the inaugural awards presentation.

The new awards themselves are based on a carefully drawn-up constitution. They are made by a General Council on the recommendation of each of five adjudicating award committees established under the scheme, one for each field. Each award committee comprises 5-9 members distinguished in its field and elects its own chairman. The General Council itself has a membership of seven, comprising the five chairmen of the award committees, the chairman of the organizing committee and, *ex officio*, the general manager of the Australian branch of Encyclopaedia Britannica Inc. The administration of the awards is thus left in the entirely independent hands of experts and the sponsoring Company is only nominally represented by one vote on the General Council. Nominations of candidates of the awards can be made by anyone to the respective award committees and meritorious nominations are then discussed by the committees at as many meetings as may be required for each committee to decide on a single candidate or very short list of candidates for final decision and endorsement by the General Council.

The composition of the Britannica Australia Award Committees is as follows:

#### GENERAL COUNCIL

Sir Leonard Huxley, vice-chancellor, Australian National University, Canberra (*chairman*); Sir Macfarlane Burnet, director, Walter and Eliza Hall Institute, Melbourne, professor of experimental medicine, University of Melbourne; Mr. H. Missingham, director of the Art Gallery of New South Wales, Sydney; Dr. W. C. Radford, director, Australian Council of Educational Research; Mr. C. W. Semmler, assistant general manager (programmes), Australian Broadcasting Commission; Mr. O. A. Guth, executive assistant in the School of Physics, University of Sydney; Mr. J. J. Salmon, general manager, Encyclopaedia Britannica Inc. (Australia) (*ex officio*); Mr. G. I. Carr (non-voting co-ordinator), Gabriel I. Carr and Associates.

#### SCIENCE AWARD COMMITTEE

Sir Leonard Huxley (*chairman*); Prof. M. Chaikin, dean of the Faculty of Applied Science, and head of the school of Textile Technology, University of New South Wales, Sydney; Prof. T. M. Cherry, president, Australian Academy of Science, professor of mathematics, University of Melbourne; Dr. D. Martyn, chief officer, Upper Atmosphere Section, Commonwealth Scientific and Industrial Research Organization, Camden, New South Wales; Prof. D. Mellor, head of the School of Chemistry, University of New South Wales, Sydney; Prof. H. Messel, head of the School of Physics, University of Sydney, and director, Nuclear Research Foundation within the University of Sydney; Sir Mark Oliphant, director of the School of Research in Physical Sciences, Australian National University, Canberra; Sir Harold Raggatt, secretary, Commonwealth Department of National

Development; Prof. R. Robertson, professor of botany, University of Adelaide.

#### MEDICINE AWARD COMMITTEE

Sir Macfarlane Burnet (*chairman*); Sir John Eccles, professor of physiology, John Curtin School of Medical Research, Canberra; Sir Clive Fitts, consulting physician, Royal Melbourne Hospital and Royal Women's Hospital; Sir Ian Douglas Miller, dean of the Clinical School, St. Vincent's Hospital, Sydney; Major-General W. D. Refshauge, Commonwealth director-general of health, Canberra; Prof. V. M. Trikojus, professor of biochemistry, University of Melbourne.

#### LITERATURE AWARD COMMITTEE

Mr. C. W. Semmler, assistant general manager (programmes), Australian Broadcasting Commission (*chairman*); Mr. V. T. Buckley, senior lecturer, Department of English Language and Literature, University of Melbourne; Mr. Geoffrey Dutton, Adelaide, South Australia; Prof. S. L. Goldberg, professor of English literature, University of Sydney; Mr. W. S. Hamilton, controller of news, Australian Broadcasting Commission; Prof. C. Quentin, associate professor of drama, University of New South Wales, and director, National Institute of Dramatic Art.

#### EDUCATION AWARD COMMITTEE

Dr. W. C. Radford, director, Australian Council for Educational Research, Melbourne (*chairman*); Prof. G. W. Bassett, professor of education, University of Queensland, Brisbane; Prof. C. A. Gibb, professor of psychology, Australian National University, Canberra; Prof. C. Sanders, professor of education, University of Western Australia, Nedlands; Dr. L. N. Short, Educational Research Unit, University of New South Wales, Sydney; Mr. W. Wood, director of special education services, Department of Education, Brisbane, Queensland; Prof. W. M. O'Neil, professor of psychology, and chairman of the professorial board, University of Sydney.

#### ART AWARD COMMITTEE

Mr. H. Missingham, director, Art Gallery of New South Wales, Sydney (*chairman*); Dr. H. C. Coombs, governor of the Reserve Bank of Australia, chairman, Australian Elizabethan Theatre Trust, chairman, Reserve Bank Board, and pro-chancellor, Australian National University; Sir Daryl Lindsay, member of the Commonwealth Art Advisory Board; Dr. Bernard Smith, Department of Fine Arts, University of Melbourne; Mr. E. Westbrook, director of the National Gallery of Victoria.

#### ORGANIZING COMMITTEE

Mr. O. A. Guth, executive assistant in the School of Physics, University of Sydney (*chairman*); Miss D. Sherwin, graduate assistant to the vice-chancellor, Australian National University; Mr. G. I. Carr, Gabriel I. Carr and Associates.

## SCALE STANDARDS IN GEOGRAPHICAL RESEARCH: A NEW MEASURE OF AREAL MAGNITUDE

By P. HAGGETT, R. J. CHORLEY and D. R. STODDART

Department of Geography, University of Cambridge

### Dynamic Character of Scale

WHEN one compares the nature of work by geographers which has been conducted within areal frameworks of different size, it becomes readily apparent that areal magnitude is not a passive quality merely distinguishing

large-scale from small-scale investigations which in other respects are similar, but that size itself imposes other indissolubly yoked characteristics which do much to colour the whole work. Indeed, the whole question of the analysis of regional and local components<sup>1,2</sup> implies that, at different scales, different parameters become

Fig. 1. Relation of the G scale to conventional measures. Scale G, the Brillouin scale, is linear and is therefore not directly comparable with scales A, B, and D. Figures in brackets after the regions indicated in scale D give the appropriate G values

dominant, different levels of generalization may be attempted, and even different problems identified.

The dynamic character of linear scale ( $A \propto L^2$ ) can be illustrated in an exaggerated but productive manner by considering the distortions involved in the reproducing of real events in model form. The inability of the model-builder to match the linear and kinematic ratios in his model is well known, and it is clear that a change of linear scale has involved drastic changes in the relationships between many of the component factors such that in many respects the model is quite unlike the real world situation it is intended to simulate. Although linear scale differences with which geographical investigations are concerned are less radical, it can be shown that here too scale is a dynamic property. A recent hydrological work by Kennedy and Brooks<sup>3</sup> has shown convincingly that whether variables in a fluvial system are identified as independent or dependent is largely a matter of the temporal or areal scales of magnitude concerned. Exploiting this work, Schumm and Lichty<sup>4</sup> have pointed out that cause-effect relationships may be obscured or even reversed depending on the span of time or areal extent under consideration in geomorphology and that, in a similar way, the system itself may be differently described. Schumm and Lichty suggest, for example, that, while a whole drainage basin may not be profitably viewed in steady-state terms, yet certain basin components may be.

It is thus possible to propose a view of areal magnitude which enables one to recognize that the scale of investigation adopted, whether consciously or unconsciously, influences the whole systematic framework of the investigation itself<sup>5</sup>. In this view, with changing areal magnitude, component factors vary in relative importance, the basic dependence or independence of the factors may change, the way in which problems are formulated may vary, the significance and opportunities of a given problem may appear in very different lights, and even different dominant problems emerge. Increasing areal coverage necessarily implies greater discarding of information and more generalization, but in even more subtle ways areal

magnitude seems to pervade and influence every feature of geographical work in such a natural manner that its influence is usually unrecognized.

### Problems of Range and Standard

In addition to the general philosophical problem of magnitude, there is the more immediate difficulty of finding a standard scale of measurement. Geographers are concerned with subjects which range in scale from continents (1,000,000–10,000,000 sq. miles) through parishes (1–10 sq. miles) to even smaller units, and although many of the more antique areal units have been dropped, the variations between the four conventional units (square miles, square kilometres, acres and hectares) are sufficiently great to make easy comparison impossible. Although in practice we may use conventional natural standards (for example, 1,000,000 acres is about the size of the County of Somerset, England; 100,000 sq. miles about the size of the State of Colorado, U.S.A., and so on) or rapidly convert the various units through tables<sup>6</sup>, the method remains cumbersome and difficult. Physical geographers, moreover, may be concerned with the measurement of objects ranging in scale down to individual sediment particles in the silt-clay range. Faced with handling sediment calibre varying over a million-fold range of sizes, sedimentologists have used various logarithmic transformations, such as Krumbein's  $\phi$  scale ( $\phi = -\log_2 D$  mm), in which large boulders ( $-10\phi$ ) and clays ( $+10\phi$ ) may both be easily accommodated<sup>7</sup>. Recent investigations of surface texture of particles using the electron microscope<sup>8</sup> have increased the linear range of geographical interest. The success of the  $\phi$  scale in sedimentology suggests that logarithmic scales provide a convenient way of collapsing differences in magnitude on to a convenient yardstick. Such scales have also been used, for example, in astronomy for measuring stellar magnitude, and in pedology for measuring pH values.

The range of interest of geographical enquiry in absolute terms may be seen with reference to a linear diagram

published by Brillouin<sup>9</sup> (Fig. 1C). This consists of a logarithmic scale ranging from  $10^{30}$  to  $10^{-50}$  cm, and includes the largest and the smallest distances so far measured (approximately  $10^{27}$  and  $10^{-13}$  cm, respectively). Within this spectrum, the area with which geographers are concerned occupies a median position, ranging from  $4.01 \times 10^9$  cm (the circumference of the Earth) down, in the case of sediments, to  $10^{-3}$ – $10^{-4}$  cm. The question arises whether any absolute units may be used to define the range of geographic interest, and to replace the arbitrary conventional units now in use.

Brillouin<sup>10</sup> has suggested we might use as a base an absolute minimum linear distance, operationally defined as that distance below which no wave or other measuring device exists to be used as a standard. The wave-length of cosmic rays is of the order of  $10^{-15}$  cm; below this length the energy quanta involved become so great as to be impossible of realization. Thus Brillouin calculates that a wave-length of  $10^{-50}$  cm would involve a mass equivalent of  $2 \times 10^7$  metric tons ( $10^{13}$  g). "Every interaction between such a wave and any physical system would involve at least one such quantum, either absorbed or emitted, and provoke an immediate catastrophe. Needless to say, this short calculation is sufficient to prove the absolute impossibility of measuring  $10^{-50}$  cm; and if he cannot measure it, a physicist will never dare speak of it"<sup>10</sup>.

However appropriate this natural standard may be for the physical sciences, there is a good case for regarding an equally fundamental unit—the surface area of the Earth—as the appropriate natural standard for geographic measurement. As Hettner argues, "geography interprets the earth as the largest region"<sup>11</sup>, and Hartshorne defined its primary concern as "... to provide accurate, orderly and rational description and interpretation of the variable character of the earth surface"<sup>12</sup>. The total surface of the globe is approximately estimated as  $1.96836 \times 10^8$  square miles (Fig. 1A), and geodetic revision seems unlikely to alter the first few integers of this estimate. The Earth's surface is thus both a natural standard and one of sufficient stability (at least in relation to the span of human history) to provide a logical unit for geographical standardization of area.

### Proposed Measure of Areal Magnitude

We propose therefore that the standard of geographical measurement shall be the Earth's surface area ( $G_a$ ), and that a scale of measurement (the  $G$  scale) shall be derived by successive subdivisions of this standard area by the power of ten. Table 1 shows the general progression of  $G$  values, while Fig. 1D shows the relation of the  $G$  scale to conventional standards of areal measurement.

$G$ scale value	Subdivision of $G_a$	Area (sq. miles)
0	$G_a$	$1.968 \times 10^8$
1	$G_a (10)^{-1}$	$1.968 \times 10^7$
2	$G_a (10)^{-2}$	$1.968 \times 10^6$
3	$G_a (10)^{-3}$	$1.968 \times 10^5$
4	$G_a (10)^{-4}$	$1.968 \times 10^4$
5	$G_a (10)^{-5}$	$1.968 \times 10^3$
$n$	$G_a (10)^{-n}$	$1.968 \times 10^{(8-n)}$

In practice, we suggest the general technique for comparing the standard (the Earth's surface) with the area under investigation is to use tables of logarithms to base 10. In view of the limited accuracy of the natural standard, values of  $G$  beyond two decimal places are unlikely to be needed in practice for which four- or five-figure tables of logarithms are likely to be sufficiently accurate.

The value of  $G$  may be given by the general formula:

$$G = \log (G_a/R_a)$$

where both  $G_a$  (the Earth's surface) and  $R_a$  (the area under investigation) are measured in the same areal unit

(for example, acres). In practice, it is more convenient to compute the value of  $G$  by subtracting the logarithm of  $R_a$  from a constant equal to the logarithm of the Earth's surface. Table 2 gives constants for four common areal standards.

Table 2

Conventional areal standard	Appropriate formula for calculation of $G$
Square miles	$8.2941 - \log R_a \text{ (miles}^2\text{)}$
Square kilometres	$8.7074 - \log R_a \text{ (km}^2\text{)}$
Acres	$11.1003 - \log R_a \text{ (acres)}$
Hectares	$10.7074 - \log R_a \text{ (hectares)}$

The advantage of the  $G$  scale as a geographical reference system stems from four characteristics. First, it uses a natural standard, the surface of the Earth, rather than existing arbitrary standards. Secondly, through its logarithmic nature it reduces a very wide range of values to a simple scale, for example running from zero (the Earth) through 10 (for an area roughly the size of Trafalgar Square) to smaller units. Thirdly, it allows ready comparison of the relative size of areas, in that regions which are different in area by a factor of 10 have values 1 unit apart on the  $G$  scale, regions which are different in area by a factor of 100 are 2 units apart, and so on. Fourthly, it simplifies the present confusion of conventional standards (Fig. 1A and B) and substitutes a simpler scale of natural values (Fig. 1D).

Against these advantages we must set the disadvantage of all new measures, unfamiliarity, and the fact that small  $G$  values indicate large areas, and vice versa, whereas we intuitively expect the reverse to be true. Other measures,

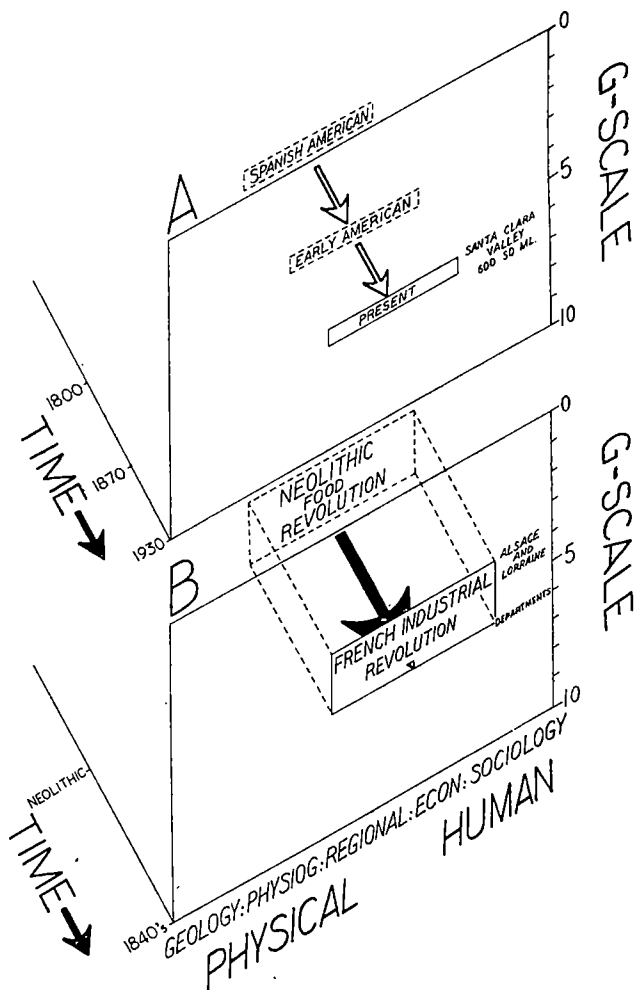

Fig. 2. Comparison of regional studies by Broek<sup>14</sup> (A) and Vidal de la Blache<sup>15</sup> (B) presented with reference to the  $G$  scale, the range of subject treatment, and the time-span under consideration

for example, British Standard sieve sizes in sediment analysis, have survived a similar problem. We do not think one solution proposed for the  $G$  scale, its reciprocal, is viable, since it makes the present scale unnecessarily complex.

### Implications for Geographical Research

Application of the  $G$  scale to existing geographical areas shows some interesting results (Fig. 1D). Values for continents range from  $G=1.06$  to  $G=1.83$  and help to correct some of the distorted size concepts which arise both from the Mercator projection and from relative accessibility (for example, Hägerstrand's<sup>13</sup> hypothesis that 'distant' areas are underestimated in size, whereas we exaggerate the relative size of nearby areas). There are, however, more fundamental implications for the whole character of geographical research.

One of the many illustrative, and even analytical, potentialities presented by the  $G$  scale is shown by a comparison of two important regional works given in Fig. 2. The investigation by Broek<sup>14</sup> of the Santa Clara Valley, California, appears here (Fig. 2A) as three regional time-slices, linked by short textural segments, in which physical and economic aspects of the area are knit into a regional treatment. Although some ranch-scale information is given, the areal scale of the investigation, at all historical periods, is fundamentally that of the 600 square mile Santa Clara Valley ( $G=5.52$ ). Contrast is provided in Fig. 2B by a similar representation of Vidal de la Blache's<sup>15</sup> classic treatment of eastern France. Here,

bounded by the two hiatuses of the Neolithic Food Revolution and the French Industrial Revolution, the region of Alsace-Lorraine is treated in the context of a time-continuum. Carrying his balanced treatment from this scale ( $G=4.12$ ) down to *Département* levels ( $G=c.6$ ), Vidal de la Blache integrates the physical and human aspects of eastern France, carrying his emphasis more deeply into the field of sociology than did Broek.

It is not difficult to imagine how the economical, standardized  $G$  scale, when used in such a comparative manner, can assist not only the convenient illustration of the scope of geographical works but also provides a tool which will aid in the analysis of their methodological bases.

## ANTIBODY FORMATION AND THE CODING PROBLEM

By PROF. FELIX HAUROWITZ

Department of Chemistry, Indiana University, Bloomington

SINCE antibodies have been recognized as typical globulins, antibody formation is essentially formation of protein. Modern views on protein biosynthesis are stated in the simplest form in the central dogma<sup>1</sup> of molecular biology which postulates that the primary structure, that is, the amino-acid sequence of the proteins, is determined by the nucleotide sequence of the nucleic acids, and that information of this type is transmitted in only one direction, from nucleic acids to proteins, and not in the reverse direction. Frequently it is also assumed that the conformation of the native protein is uniquely determined by its amino-acid sequence and that no further genetic information is required for the folding of the peptide chain<sup>2</sup>.

Theories of antibody formation were formulated before the advent of modern concepts of the biosynthesis of proteins. They have usually been classified as: (a) selective theories; (b) template or instructive theories. According to the former, proposed first by Ehrlich (1900), the antigen selects from a number of pre-formed 'receptors' those which can specifically combine with the antigen; combination of these receptors with the homologous antigen stimulates their regeneration and the secretion of free receptors into the circulation where they appear as antibodies. In the template theories<sup>3-7</sup> it is claimed that the antigen molecules interfere with the normal process of globulin formation in such a manner that the newly formed globulin molecule (antibody) fits complementarily to the specific determinant group of the antigen molecule.

Numerous theories of antibody formation have been advanced, each of them modifying one or more of the statements of the original selective or template theory. Most of the immunological phenomena can be explained satisfactorily by any of the many variants proposed. However, in spite of intensive experimental work in this

field of research, it has not yet been possible to make a final decision between the selective role of the antigen and its role as a template. These two functions of the antigen are fundamentally different when applied to the biosynthetic process. If the antigen has merely to select between different types of preformed 'receptors', then it is not necessary to postulate interference of the antigen in the process of globulin biosynthesis, or any modification of this process. On the other hand, if the antigen interferes in this process in such a manner that antibodies are formed instead of normal globulins, the question arises in which phase of protein synthesis this interference occurs and how the complementary conformation of the combining group of the antibody is accomplished. The purpose of this present article is to answer these questions and to show that the template theory can be expressed in terms of modern molecular biology.

### Template Role of the Antigen and the Coding Problem

Breml and Haurowitz in 1930<sup>8</sup> attributed the formation of antibodies to interference of the antigen with the biosynthesis of serum globulins from their amino-acid precursors. Similar views were advanced independently by Alexander<sup>4</sup> and Mudd<sup>5</sup>. The high specificity of the antigen-antibody interaction was attributed by me<sup>6</sup> to the presence in antibodies, but not in normal serum globulins, of groups which are "spatially adjusted to the determinant groups of the antigen and therefore can approach it very closely". Pauling<sup>7</sup> in 1940 suggested that the antigenic determinant interferes only with the folding of the peptide chains which form the antibody molecules, but that it does not alter their amino-acid composition. The work of Porter<sup>9</sup> and Edelman<sup>10</sup> has

revealed that the typical 7S antibody molecule consists of two heavy *A* (or *H*) and two light *B* (or *L*) chains; their molecular weights are approximately 50,000 and 25,000 respectively. They are held together by disulphide bonds. Karush<sup>11</sup> assumes that the conformation of the antibody molecule is determined by the formation of these disulphide bridges and that their position is different in antibodies of different specificity.

*A priori* a template molecule might interfere with any of the principal steps in protein biosynthesis. These are: (a) the replication of DNA molecules; (b) the transcription of the DNA code into the nucleotide sequence in RNA molecules; (c) the translation of the latter into amino-acid sequences; (d) the folding of the peptide chains which results in the formation of the specific combining site of the antibody molecule; (e) the combination of the two *A* (or *H*) chains and the two *B* (or *L*) chains to form the antibody molecule of the composition  $A_2B_2$  (or  $H_2L_2$ ).

The last of these events (phase *e*) can be excluded from our discussion since it has been demonstrated that the four-subunits recombine *in vitro* spontaneously to yield biologically active antibody molecules<sup>12-14</sup>, and that this process does not require the presence of antigen.

We can also exclude interference of the antigen in phase *a* (replication of DNA) since this would involve mutagenic action of the antigen. The principal objection to such a process is the failure of antibody-forming cells to produce antibody-forming daughter cells in the absence of antigen. When antibody-forming cells of a sensitized animal are transferred to a new-born or irradiated animal which has not the ability to form antibodies, they continue to multiply in the recipient and to form antibody, but lose this ability after a number of transfers from one to another recipient<sup>15,16</sup>; antibody formation is resumed after the administration of a small amount of the antigen. Similar observations have been made in antibody-forming tissue cultures<sup>17</sup>. Evidently, the presence of antigen is necessary for the production of antibody in the daughter cells of antibody-forming mother cells. We have therefore no reason to assume a mutagenic action of the antigen.

Modification of phase *b* (transcription from DNA to RNA) or *c* (translation from RNA to amino-acids) should result in changes of the composition and sequence of the amino-acids in the antibody molecule. Occurrence of such changes was indicated first by small but significant differences in the peptide maps of antibodies against human and horse serum albumin<sup>18</sup>, and against different types of pneumococcal polysaccharides<sup>19</sup>. Since these antigens contain a number of different determinant groups, the antibodies formed by their injection are heterogeneous mixtures of antibodies directed against the different determinants. It is therefore difficult to decide whether the differences in the peptide maps reflect chemical differences in the antigenic determinants or merely reflect different distribution of the injected antigens in the organism and antibody formation in different organs or cells. Some of these difficulties are avoided by the isolation of hapten-specific antibodies which combine with small well-defined determinant groups, and by a comparison of their amino-acid composition and sequence. Antibodies of this type have been produced in my laboratory by injecting rabbits with bovine serum proteins coupled to the anionic diazobenzenearsonate (Ars) or the cationic diazobenzene-*N*-trimethylammonium ( $R_4N$ ) groups and separation of the hapten-specific from the protein-specific antibodies. Koshland and Englberger<sup>20</sup> found small but significant differences in the amino-acid composition of anti-Ars and anti- $R_4N$ . Similarly we found differences in the peptide maps of the two hapten-specific antibodies<sup>21-23</sup>. These differences were extremely small; most of the peptide spots of the tryptic digests of anti-Ars and anti- $R_4N$  were identical. The observed differences cannot be caused by genetic differences, because they were also found when the two azoproteins were injected into

the same animal<sup>20-24</sup>, or when a doubly-labelled azoprotein containing both Ars and  $R_4N$  groups was injected<sup>24</sup>. The latter experiment excluded differences in the organ distribution pattern of the two antigens. It has not yet been possible to decide whether the small differences in the amino-acid composition and similar small differences in the peptide maps of the two hapten-specific antibodies reflect differences in their specific combining groups. The near-identity of the peptide maps indicates clearly that the anti-Ars and the anti- $R_4N$  antibody molecules have numerous identical amino-acid sequences in their molecules.

Although the differences between the two hapten-specific antibodies are small, they seemed to indicate interference of the antigen in the phases *b* (transcription from DNA to RNA) or *c* (translation of the code). Since we do not know of any long-range forces in biological systems, we would have to postulate the presence of antigenic determinants in the vicinity of the sites of amino-acid incorporation. This postulate is in agreement with the finding of isotopically labelled antigenic determinants in the microsomal and mitochondrial fractions of spleen and liver cells<sup>25-27</sup>, and with combination of antigen fragments with sRNA or other RNA fractions<sup>28,29</sup>. However, even if we assume a modification of the amino-acid sequence by interference of the antigenic template with the phases *b* and *c*, it is still difficult to understand why such a change in amino-acid sequence should result in the production of a peptide chain which spontaneously would fold in such a manner that the complementary combining group would be formed.

In considering this problem it must be kept in mind that the conformation of the combining site of the antibody is determined principally by the three-dimensional shape of the antigenic determinant, much less by its charge, polarity and other properties. This conclusion is based on the ability of antibodies to differentiate between *o*-, *m*- and *p*-isomers, between *L*- and *D*-isomers and also between *cis*- and *trans*-derivatives of otherwise identical antigenic determinants<sup>30</sup>. The great importance of the shape of the antigenic determinant is clearly demonstrated by the observation that antibodies produced by the injection of an azoprotein containing the positively charged azophenyl-*N*-trimethylammonium group,

combine also specifically with the uncharged azophenyl-trimethylmethane group,  $-N=N-C_6H_4-C(CH_3)_3$  (ref. 31), since the shape of the  $-C(CH_3)_3$  group is identical with that of the  $-\overset{+}{N}(CH_3)_3$  group. The question to be answered by a satisfactory theory of antibody formation is, therefore: In which phase of the biosynthetic process is information concerning the shape of the antigenic determinant transmitted to the sites of protein biosynthesis, and how does this transmittance occur?

In view of the absence of long-range forces, it must be postulated that the folding of the peptide chains (phase *d* of the biosynthetic process) occurs in the immediate vicinity of the antigenic determinant. This is merely a restatement of Pauling's<sup>7</sup> original postulate that the antigenic determinant acts as a template for the folding of the peptide chains. At first sight this postulate seems to be incompatible with the observed differences in amino-acid sequence and also with the claim that the conformation of the peptide chain is determined by its amino-acid sequence<sup>2</sup>, which in turn depends on the nucleotide sequence of the messenger-RNA molecules. Most of these difficulties disappear when the statement concerning dependence of the conformation on the amino-acid sequence is replaced by the statement that conformation and amino-acid sequence are interdependent, and that changes in conformation caused by a template might secondarily lead to changes in the amino-acid sequence.

Fig. 1. The diagram shows five ribosomes linked to each other by a long thread of messenger-RNA (broken line). The upper part of the diagram represents the biosynthesis of a peptide chain of normal  $\gamma$ -globulin, the lower part the analogous process in the presence of an antigenic determinant (dark area on the third ribosome). The end of the growing peptide chain which carries the terminal  $\alpha$ -amino (or acetylamino) group is marked by the letter N, the specific combining site of the growing chain of the peptide chain; it may just as well be near the N- or C-terminus. In the diagram the transfer of information concerning only the shape of the antigenic determinant is delineated. If the determinant contains an anionic or cationic group, electrostatic interaction may result in the incorporation of an amino-acid which contains a group the  $pK$  value of which is high or low, respectively. A mechanism of this type has been suggested earlier<sup>42</sup> and is supported by experimental work of Pressman *et al.*<sup>48</sup>

We assume, in accordance with these views, that antigenic determinants are bound to some of the ribosomes or to the messenger RNA molecules as shown in Fig. 1, and that the determinant group, which is usually rigid and polar, affects the biosynthetic mechanism in two ways: (1) dipole induction and other intermolecular forces originating from the template induce a small portion of the newly formed peptide chain to fold over the surface of the antigenic determinant and thus to produce a complementary pattern; (2) while most of the aminoacyl residues are incorporated into the peptide chains of the antibody molecule in the sequence dictated by the nucleotide sequence of the messenger-RNA, deviations from the code occur during the formation of the combining site; only those aminoacyl residues are incorporated which allow the peptide chains to fold complementarily over the antigenic determinant, whereas other aminoacyl-sRNA complexes are rejected. Since the process of amino-acid incorporation is exergonic and practically irreversible, the rejection of any unsuitable aminoacyl residue must occur before the next amino-acid is incorporated. The incorporation process has been described appropriately as displacement of the terminal tRNA residue of an sRNA-peptide ester by the incoming aminoacyl-sRNA complex<sup>32,33</sup>. The rejection mentioned obviously may be considered as the inability of an unsuitable aminoacyl-sRNA complex to displace the terminal RNA residue.

Antibody formation, according to this view, involves primarily direct interference of the antigenic template in the case of folding of peptide chains of the biosynthetic process and, by rejection of unsuitable aminoacyl residues, indirectly with the translation process (case c). Most probably, the process occurs in the same cells in which the normal  $\gamma$ -globulins are formed, and is controlled by the same genetic apparatus, the same types of DNA and RNA, as shown by the occurrence of the same genetic markers in antibodies and in normal globulins<sup>44</sup>.

Our postulate that the antigenic template, by dictating definite conformation, may alter the normal amino-acid

sequence is contradictory to the simple form of the original central dogma and may appear heretical. However, modifications of the coding process by external factors have been demonstrated by several authors<sup>35-37</sup> and may be quite frequent. Processes of this type have been discussed extensively by Dean and Hinshelwood<sup>38</sup> and by Commoner<sup>39</sup>. The possibility of deviations from the central dogma in the biosynthesis of antibodies has been pointed out earlier by Spiegelman<sup>40</sup> and Me<sup>41</sup>.

The theory presented here does not involve the claim that each antigenic determinant induces in all organisms formation of the same complementary group of identical amino-acid composition. Peptide maps of hapten-specific antibodies against the azophenylarsenate residue are different in chicken and in rabbit antibodies<sup>23</sup>. Differences may also exist between antibodies formed in different organs or cells of an animal. Evidently, the complementary pattern of the combining group can be produced by different amino-acid sequences. It would be strange if the process of template action were limited to antibody formation. 'Physiological' templates may be responsible for complementary patterns in enzymes, hormones and other biologically active protein molecules.

### Objections Raised against the Template Role of the Antigen

The principal objections raised against the template theory of antibody formation are that it cannot explain: (a) antibody formation after elimination of all the antigen; (b) the characteristic differences between the primary and the secondary response; (c) the ability of the organism to differentiate between self and non-self<sup>42</sup>. The following paragraphs (a)-(c) show that these objections are based on different interpretations of experimental results rather than on divergent results.

(a) The claim that antibody formation occurs after elimination of all the antigen was originally based on the assumption that all the antigen is rapidly eliminated. While it is true that cellular or bacterial antigens do not survive as such, experiments in my laboratory<sup>25-27</sup> and in other laboratories<sup>28,29</sup> have shown that isotopically labelled determinant groups of the antigen persist in the organs of the reticuloendothelial system for many months. In experiments with <sup>35</sup>S- or <sup>14</sup>C-labelled azoprotein antigens the half-time of antigen elimination from the spleen increased from a few days shortly after a single injection to 5-7 weeks a few months after the injection<sup>26</sup>. Since the antibody titre in these experiments decreased at a similar rate<sup>43</sup>, we have every reason to assume that retention of antigen and extent of antibody formation are correlated with each other.

(b) It is a well-established experimental fact that the primary antibody response depends on the form in which the antigen is administered, and that the intensity of response to soluble antigens is increased when these antigens are made insoluble by adsorption to adjuvants. The higher antigenicity of the insoluble antigen particles is evidently due to the fact that only these stimulate phagocytosis and are thus rapidly incorporated into macrophages and other phagocytic cells, whereas the soluble antigens circulate for a long time in the body fluids. The intensity of the anamnestic response is frequently attributed to the immunological memory of the cells stimulated in the primary response. This view is based on the fact that the precipitin test becomes negative a few weeks after a primary reaction. However, continuous formation of small amounts of antibody in the circulation for more than a year after a single injection of bovine serum albumin or ovalbumin can be detected by means of the highly sensitive passive haemagglutination reaction, that is, the agglutination of antigen-coated erythrocytes<sup>50</sup>. Re-injection of the antigen a few weeks or months after the first injection results in the immediate

ormation of antigen-antibody complexes which, in contrast to the soluble antigen molecules, are rapidly eliminated from the circulation, trapped in phagocytic cells, and therefore elicit a much stronger antibody response than the primary injection of soluble antigen<sup>43</sup>. The 'memory cells', according to this view, are merely cells which, owing to their content of antigen fragments, continue to elicit the formation of small amounts of antibody.

(c) 'Self-recognition' is a more recent term for the phenomenon designated by Ehrlich as "horror autotoxicus", that is, the inability of the organism to form antibodies against its own proteins. This idea has lost its general validity by the discovery of auto-antibodies against the eye lens, the brain, testis, thyroid gland, kidney and other organs the proteins of which, owing to injury, penetrate into the circulation. In some instances these tissue proteins may undergo denaturation and become 'foreign'<sup>44</sup>. Frequently, auto-antibody formation is a physiological process which aids in the removal of products of cell damage<sup>45</sup>. The idea of self-recognition is further invalidated by the observation that rabbits injected repeatedly with large amounts of bovine serum albumin fail to form anti-bovine serum albumin so long as bovine serum albumin circulates in their blood<sup>46</sup>. Their inability of forming anti-bovine serum albumin parallels their inability of forming antibodies against their own serum albumin. Both phenomena can be attributed to the continued presence of these proteins in the blood plasma.

Summarizing, it may be said that the prolonged antibody formation and the intensity of the anamnestic reaction are explained by the template theory of antibody formation just as well as by the selective theories, and that the concept of self-recognition has lost its validity as a general principle, and therefore cannot be used as a criterion for the validity of any theory of antibody formation.

### Selective Theories of Antibody Formation

Ehrlich's ingenious theory of preformed receptors was advanced at a time when nothing was known of the nature of antibodies. In 1931 Browning<sup>47</sup> still warned that the term antibody "implies merely the acquisition . . . of properties, . . . not . . . a chemically defined substance". The idea of preformed receptors was satisfactory at a time when only a small number of antigens, mostly pathogenic bacteria or animal proteins, were known. The number of potential antigens were enormously increased by Landsteiner's<sup>30</sup> discovery that the specificity of antibodies is directed against definite chemical groups of the antigen molecules, and that numerous synthetic groups such as aromatic sulphonates, arsonates or quaternary bases are excellent determinants; antibodies against an almost unlimited number of these synthetic products can be produced by coupling the synthetic determinants to proteins and injecting the conjugated proteins into the animal organism. It is difficult to believe that the organism should contain preformed receptors against thousands of these artefacts of the chemical laboratories.

The same objection can be raised against modifications of Ehrlich's theory, particularly the natural selection theory proposed in 1955 by Jerne<sup>48</sup>, and the clonal selection theory advanced in 1959 by Burnet<sup>49</sup>. The role of Ehrlich's receptors was in these theories assigned to 'competent' cells, that is, lymphoid cells, each of them endowed with the ability of forming only one type of antibody. It was further assumed that this ability, like other genetic characteristics, is transmitted to the daughter cells and that antibody production can occur in the absence of antigen once the multiplication of the respective cell type has been stimulated by the antigen. Since multiplication of somatic cells is an asexual process, the descendants of each of the stimulated mother cell form a clone. The antigen would select that clone which produces the homologous antibody. The intensity of the antibody

response in re-injected animals was attributed to a large number of descendants of the cells stimulated by the first injection of antigen.

The original clonal selection theory was abandoned when it was found that single cells isolated from an animal sensitized with two different antigens formed occasionally two different antibody types<sup>50,51</sup>, that the bulk of the cells which formed only one or the other type of antibody were randomly intermingled and did not appear in separate clusters as would be expected in the formation of clones<sup>52</sup>, and that a pure clone of mouse cells injected into irradiated mice was able to form antibodies against four different antigens<sup>53</sup>.

In considering difficulties of the clonal selection theory, Burnet<sup>42</sup> stated that "the only escape would be to postulate a rate of random mutation of pattern as high as . . . in early embryonic life". Indeed, Burnet<sup>54</sup> has recently proposed a new theory which might be designated as 'random mutants theory'. In this theory the postulate of re-adapted cells has been abandoned and replaced by the claim that rapid random somatic mutation is the only source of immunological pattern and that "clonal selection, positive or negative, can mould the population of mutants to provide the . . . adapted structure . . .". Several objections can be raised against this new theory: (a) Rapid mutations in adult animals have not been observed; the rapid mutations in developing embryos occur unidirectionally toward differentiation, but not randomly. (b) If the cells endowed with the ability of antibody formation would continuously undergo rapid mutations, they would also rapidly lose their specificity and it would be difficult to explain the intense anamnestic reaction unless the antigen persisted in the cells as postulated by the template theory, but denied by the selective theories. (c) It is difficult to reconcile the assumption of continued rapid mutations of the  $\gamma$ -globulin producing cells with the fact that the peptide chains of the antibodies of an individual have the same genetic markers as the analogous chains of his normal  $\gamma$ -globulins.

Most of the objections raised against cellular and clonal selection have been avoided by Jerne<sup>55</sup>, who has withdrawn his original postulate<sup>48</sup> of cellular selection and has replaced it by the assumption that the genetic apparatus of each competent cell contains "a complete dictionary against all foreign antigens" and that selection occurs intracellularly. A mechanism of this type had been suggested earlier by Szilard<sup>56</sup>, who assumed that repressor molecules interfere with the production of specific proteins (antibodies) at the genetic level, and that diffusion of the antigen into the cell causes derepression. Similarly, Jerne<sup>56</sup> suggests that specific protein synthesis is accomplished by the repression of RNA-messages arriving from uninhibited genes. The diagram in Fig. 1 makes it unnecessary to invoke the presence of specific repressors since the antigenic determinant modifies directly that part of the antibody molecule which forms the combining site. However, if there were individual differences between the ribosomes of a cell, and if the antigenic fragment could combine with only some but not with other ribosomes, a selective factor would be introduced into the template model depicted in Fig. 1. At present we have no information about any specific differences within the ribosome population of a cell.

### Conclusion

The purpose of this article is to demonstrate that the template theory of antibody formation is reconcilable with the present views on coding and protein biosynthesis. The finding of the injected antigen in the microsomal fraction of spleen and liver indicates that the antigenic determinants are close to the ribosomal sites of amino-acid incorporation. It is assumed that intermolecular forces between the rigid, polar antigenic determinant and the nascent peptide chain lead to: (1) the rejection of

amino-acyl residues which would not allow the peptide chain to fold complementarily over the template; (2) their replacement by amino-acyl residues which enable the peptide chain to form the complementary combining site of the antibody molecule. It is assumed that in this manner the amino-acid sequence dictated by the messenger-RNA is modified in that part of the antibody molecule which combines specifically with the antigenic determinant. Template action of this type may also be involved in the biosynthesis of enzymes, protein hormones or other protein molecules.

The template theory of antibody formation is supported by the persistence of the antigen over long periods of time, and by the demonstration that antibody formation is possible only in the presence of antigenic determinants and ceases after their elimination. I believe I have shown that the template action of the antigen satisfactorily explains antibody formation, and that it is not necessary to invoke random mutation of lymphoid cells and selection of suitable mutants by the antigen as responsible for antibody formation. Nor is it necessary to postulate the presence of 'memory cells' in order to explain the anamnestic reaction. Finally, serious doubts have been raised whether the organism has the ability of differentiating quite generally foreign proteins from autologous proteins.

The experiments on which this article is based were supported by research grants GM-01852 of the National Institutes of Health and G-16345 of the National Science Foundation, and by contracts of Indiana University with the Office of Naval Research, Nonr-3104(00), and the Atomic Energy Commission, AT(11-1)-209.

## FOOD PREFERENCE AND SENSITIVITY OF TASTE FOR BITTER COMPOUNDS

By DR. E. V. GLANVILLE and DR. A. R. KAPLAN

Laboratory of Medical Genetics, Cleveland Psychiatric Institute, Cleveland, Ohio

THE acceptance of one type of food and the rejection of another depend on a variety of factors, including the physiological state of the body as well as social custom and experience. The relative sensitivity of taste perception has also been shown to be important. Fischer *et al.*<sup>1</sup> have found that in a group of 'college'-age subjects the percentage of foods disliked from a list of 118 was significantly correlated with the taste sensitivity for quinine and probably also with that for 6-n-propylthiouracil (PROP), but not for sucrose, sodium chloride or hydrochloric acid.

The present investigation resembled the earlier one in that taste sensitivities to quinine and PROP were determined, but differed in the use of a larger and older population and in the method of estimating food preferences. A

questionnaire was used which was designed to reduce, so far as possible, the influence of social custom by using a list of a few carefully selected foods all of which are in wide use locally and which are commonly prepared in a variety of forms. Subjects were rated according to their preference for which of three alternate ways they preferred a given food to be prepared. In effect, a choice was offered between mild, moderate and strongly tasting methods of preparing certain foods.

The sample consisted of 187 adult individuals, 51 males and 136 females. All were of European descent and their ages ranged from 22 to 66 with an average of 38. Contact was made with the majority of subjects through the Cleveland Area Twin Registry. The remaining subjects were associated with the staff at the Cleveland Psychiatric

Institute, and were selected on the basis of availability. The sample included 39 husband-wife pairs, 16 pairs of monozygotic twins, and 10 pairs of dizygotic twins.

Taste thresholds (the lowest concentration of the test solutions which could be distinguished from water) were determined by the method of Harris and Kalmus<sup>2</sup> with several modifications<sup>3</sup>. The method involved separating by taste randomized sets of eight cups, four of which contained 5 ml. of test solution and four distilled water placebo. Relatively dilute solutions were tasted first and the concentration was increased gradually until the subject could distinguish correctly between the two sets of cups. The modifications included the use of distilled water as the solvent and a mouth rinse before tasting each cup.

Solutions were made up as follows: *PROP*, 1.0212 g 6-*n*-propylthiouracil (Mann Chemicals) dissolved in 1 l. water gave solution number 14. This was an almost saturated solution and had a concentration of  $6.0 \times 10^{-3}$  M. Serial doubling solutions then yielded the lower solution numbers down to 1 ( $7.32 \times 10^{-7}$  M). *Quinine*, 1.1744 g 1-quinine sulphate (U.S.P.) dissolved in 1 l. water gave solution number 13. Dilutions were then made as for *PROP*. A solution of a given number of either compound had the same molar concentration. Subjects were tested once and the threshold for quinine was determined before that of *PROP*. This method of determining thresholds has been shown to be reliable and repeated tests show little intra-test variation<sup>3</sup>.

Food preferences were determined by means of a questionnaire divided into two parts:

(A) A list of widely used foods which are commonly prepared in a variety of ways, so as to provide a graded series ranging from mild, through intermediate to strongly tasting. Subjects were instructed that "several common foods and drinks are listed below. Each may be prepared in a number of different ways. Please indicate on the list below which of the three alternate choices you prefer". The list with the alternative choices was as follows, except that the choices were randomized: (1) Coffee: with more than 1 spoon of cream/with 1 spoon of cream/black, no cream. (2) Coffee: with more than 1 spoon of sugar/with 1 spoon of sugar/no sugar. (3) Cheese: American/Longhorn or Swiss/blue cheese. (4) Cheddar cheese: mild/medium/sharp. (5) Salad dressing: mild/oil and vinegar/roquefort or blue cheese.

Scores were determined as follows: questions 1 and 2 were treated as a single question as both referred to coffee. One point was given for a choice of either more than 1 spoon of cream or sugar or 1 spoon of cream and 1 spoon of sugar. One spoon of cream or 1 spoon of sugar was given 2 points, and black coffee without sugar 3 points. For questions 3, 4 and 5, 1 point was given for the first choice, 2 points for the second and 3 for the third. The minimum score was therefore 4 points (mildest choice) and the maximum 12 (strongest tasting choice).

(B) A list of 5 foods. Subjects were asked to answer 'yes' or 'no' to whether they liked: grapefruit juice, lemon juice, sauerkraut, vinegar and horse-radish.

Verbal explanations of the questionnaire were given if required and, if a food was not customarily consumed, the subject was requested to indicate his preference if he would take it.

The entire food-preference questionnaire was given to 181 subjects. Of this number 15 could not complete Part B because they were unfamiliar with one or more of the foods listed. Incomplete forms were not counted, leaving a total of 166 complete scores on Part B. Six subjects could not complete Part A for the same reason, but an additional 12 subjects were given Part A only, as Part B was added after the experiment had begun. The total number to complete Part A was therefore 187.

Results relating to Part A of the food questionnaire will be considered first. The mean taste thresholds with their standard errors for quinine and *PROP* for subjects who preferred the mild, medium and strongly tasting

Table 1. MEAN TASTE THRESHOLDS WITH THEIR STANDARD ERRORS FOR SUBJECTS SELECTING MILD, MEDIUM AND STRONG TASTING CHOICES IN QUESTIONS 1-5 ON THE FOOD QUESTIONNAIRE

Question No.		Choice of foods tasting		
		Mild	Medium	Strong
Quinine	1 and 2	(100) 5.87 ± 0.19	(42) 5.65 ± 0.32	(45) 5.82 ± 0.27
	3	(78) 5.21 ± 0.19	(82) 6.17 ± 0.19	(27) 6.33 ± 0.48
	4	(84) 5.23 ± 0.20	(46) 5.96 ± 0.25	(57) 6.49 ± 0.24
	5	(52) 5.58 ± 0.29	(84) 5.66 ± 0.20	(51) 6.24 ± 0.24
	1 and 2	(100) 9.29 ± 0.25	(42) 9.28 ± 0.41	(45) 10.24 ± 0.37
<i>PROP</i>	3	(78) 8.68 ± 0.26	(82) 10.20 ± 0.27	(27) 10.11 ± 0.54
	4	(84) 8.74 ± 0.25	(46) 9.52 ± 0.32	(57) 10.77 ± 0.26
	5	(52) 8.84 ± 0.37	(84) 9.68 ± 0.25	(51) 10.06 ± 0.38

No. in each group are shown within parentheses.

choices in questions 1-5 are shown in Table 1. It is apparent that taste sensitivity for quinine and *PROP* is more important in determining preference in questions 3, 4 and 5 than in determining choice of the ways coffee may be prepared (questions 1 and 2).

The total scores on Part A of the food questionnaire for the total sample have been tabulated with the taste thresholds for quinine in Table 2 and for *PROP* in Table 3. The correlation coefficients between the thresholds for quinine and *PROP* and the food-preference scores are shown in the first column of Table 4. There are highly significant positive correlations between high scores on the food questionnaire (that is, a preference for strongly tasting foods) and high taste thresholds (that is, insensitive taste) of both quinine and *PROP*. Table 4 also shows that the thresholds for quinine and *PROP* are themselves correlated. The partial correlation coefficients for the three comparisons were therefore calculated, and are shown in the second column of Table 4. The correlation between food preference score and quinine threshold was then no longer significant, but that between food score and *PROP* threshold remained significant.

Results from Part B of the food-preference questionnaire were analysed by calculation of the linear regression coefficients of taste thresholds on number of foods disliked. The coefficient with quinine was found to be  $0.319 \pm 0.114$

Table 2. TASTE THRESHOLDS FOR QUININE AND SCORES ON PART A OF FOOD-PREFERENCE QUESTIONNAIRE

Table 4. TOTAL AND PARTIAL CORRELATION COEFFICIENTS WITH THEIR STANDARD ERRORS BETWEEN THRESHOLD FOR QUININE AND *PROP* AND THE SCORE ON PART A OF THE FOOD-PREFERENCE QUESTIONNAIRE. (Data from Tables 2 and 3)

	Correlation coefficients	
	Total	Partial
Quinine/food score	+0.262 ± 0.068	+0.082 ± 0.073
<i>PROP</i> /food score	+0.366 ± 0.064	+0.277 ± 0.068
Quinine/ <i>PROP</i>	+0.540 ± 0.052	+0.497 ± 0.055

and with PROP  $0.480 \pm 0.146$ . Both these values are significantly different from zero, and support the conclusion<sup>1</sup> that there is a positive association between increasing number of foods disliked and increasing taste sensitivity.

The sample included 39 husband-wife pairs. The members of these pairs are not closely related genetically and there is no significant correlation between their scores for quinine or PROP in spite of the fact that they have shared a common environment for varying lengths of time. A significant positive correlation was observed between the scores on the food questionnaire of husbands and wives. On Part A of the questionnaire the correlation coefficient was found to be 0.482 (significant for  $N=39$  at the 0.01 level). The 16 pairs of monozygotic twins in the sample were all married and had lived apart for varying lengths of time. Their scores on Part A of the food-preference form were found to be highly correlated (0.70, significant for  $N=16$  at the 0.01 level). The scores on Part A of the questionnaire for 10 pairs of dizygotic twins, 8 pairs of whom lived apart, showed an insignificant correlation of 0.18.

Both males and females showed a positive correlation between preference for mild-tasting foods and relatively sensitive perception of the taste of quinine and PROP. The males showed a somewhat higher correlation than the females, but the difference was not statistically significant.

Taste sensitivity for PROP is closely associated with that for phenylthiourea (PTC)<sup>2</sup>, which in turn is associated with that for a variety of thiourea and thioamide compounds<sup>3</sup>. Taste thresholds for all these compounds appear to be largely determined by the same pair of genes. The relative proportion of the two genes varies in different populations and the system provides one of the classic examples of polymorphism. The equilibrium between the genes must be of great antiquity as the polymorphism has been identified among apes<sup>4</sup>. The factors which maintain the balance are not clear. Many thiourea and thioamide compounds have anti-thyroid properties and some of them occur naturally in vegetables, particularly in members of the cabbage family<sup>5</sup>. It has been suggested that the existence of the PTC-PROP tasting genes in human populations is associated with the ability to taste these toxic products in food<sup>6</sup>.

The flavour of the majority of foods is the result of a medley of tastes and odours, and it may at first seem surprising that the choice of certain foods is correlated with taste sensitivity to a single compound such as PROP. However, sensitivity to PROP has been shown to be correlated with taste sensitivity to a wide variety of

other compounds, including those tasting bitter, salty, sour and sweet<sup>7</sup>. The association between taste and odour sensitivities, if any, has received little investigation.

Repeated determinations of the taste threshold of an individual have shown that under controlled conditions the thresholds for PROP and quinine are relatively stable characteristics<sup>8</sup>. However, a number of factors are known to effect thresholds for these compounds. For example, there is a gradual decline in sensitivity with increasing age<sup>9</sup>. Heavy smoking habits are associated with relative taste insensitivity<sup>9</sup> and duodenal ulcer is associated with increased sensitivity to PROP<sup>10</sup>. Increased sensitivities in the four taste modalities, salt, sweet, sour and bitter, have been reported for patients suffering from cystic fibrosis<sup>11</sup> and adrenal insufficiency<sup>12</sup>. In some women, taste sensitivity for PROP and quinine fluctuates with the phases of the menstrual cycle<sup>13</sup>.

Our investigation has revealed social influences on food preference as well as demonstrating the importance of perceptive factors. A correlation in food preference between husband and wife was apparent in spite of the absence of correlation between their taste thresholds. We may note, in passing, that for our 39 husband-wife pairs the correlation between PROP threshold and food preference score was 0.495 for husbands but only 0.335 for wives. This is not a statistically significant difference, though one may surmise jestingly that the woman who stirs the pot moulds her preferences to cater for the tastes of her husband rather than for her own.

We wish to acknowledge the interest and valuable suggestions of Dr. Roland Fischer of the Columbus Psychiatric Institute. This work was supported by grants from the National Institutes of Health, U.S. Public Health Service, HD 00581-02 (A. R. K. and R. Fischer), and GRS 05563 (Cleveland Psychiatric Institute); and by a grant from the Council for Tobacco Research—U.S.A. (A. R. K. and R. Fischer).

## OBITUARIES

### Dr. F. J. Richards, F.R.S.

WITH the death, after prolonged illness, of Dr. F. J. Richards on January 2, 1965, Britain has lost an outstanding plant physiologist, and his colleagues a much-valued friend. He was educated at Burton-on-Trent Grammar School and then entered the University of Birmingham, where he read botany and biochemistry, graduating with honours in 1924. Two years later, after a period of research on fungal respiration at Birmingham, he joined the staff of the Institute of Plant Physiology of the Imperial College of Science and Technology, London, under the directorship of Prof. V. H. Blackman. Located at Rothamsted from this time, he began his close collaboration with the late Prof. F. G. Gregory in the field of mineral nutrition of plants. With his extraordinary thoroughness, Richards examined the syndromes of deficiency in the barley plant (especially of phosphorus and potassium) in all its aspects: growth analysis, rates

of respiration and photosynthesis, water content, carbohydrate and nitrogen metabolism, the effects of other cations, in particular the partial replacement of the essential role of potassium by rubidium, etc. These investigations established his international reputation and continued, in collaboration with his students, until his death. More recently, the discovery that the amide putrescine is accumulated under potassium deficiency conditions has led to further important metabolic and enzymatic investigations.

In 1930, still in connexion with his Birmingham interests, and with the assistance of his wife, Richards followed up R. H. Yapp's investigations on the rates of accretion in the salt marshes of the Dovey Estuary. In the analysis of the data, he used the then new statistical techniques devised by R. A. Fisher, and became one of the first to introduce such methods into ecological problems. His interest in statistics led him to devise a method for the graphic representation of the results of factorial

Dr. R. F. A. Dean

experiments, which enables the immediate visual appreciation of their main effects and their interactions.

Richards's considerable mathematical ability found another outlet in the investigation of phyllotaxis. What was initially a hobby developed into a serious investigation. Taking into account the radial as well as the tangential spacing of leaf primordia at the apex, he was able to derive a function describing phyllotaxis uniquely in terms of a single index which grades smoothly from one order of phyllotaxis to the next and is applicable to all systems. A simple transformation allows the index to be applied to a conical surface when the apical angle is known (equivalent phyllotaxis index). Application of these techniques to data derived from serial sections of growing points enabled detailed analysis to be made of rates of growth of the various parts of the apex, its changing shape at different developmental stages of the plant, etc. These developments have placed the quantitative measurement of phyllotaxis on a completely new basis and represent the greatest advance in this field for many years. Quite recently, Richards developed a flexible, generalized growth function of great utility which is suitable for a considerable diversity of data.

In 1958, when the late Prof. F. G. Gregory retired from the chair of plant physiology and the directorship of the Institute of Plant Physiology, the Institute was dissolved, and Richards took over the research group located at Rothamsted as director of the new Agricultural Research Council Unit of Plant Morphogenesis and Nutrition formed for this purpose, which was later moved to Wye College.

Richards was one of the most modest of men and of a rather shy disposition; thus it was a particular pleasure to his friends when his achievements were recognized by his election to the Royal Society in 1954. He had a delightful, gentle sense of humour which enlivened many a tea-time discussion in the laboratory. In spite of his usual reticence, he could be very firm in any controversial matter where scientific principle was concerned. With his acutely critical mind he would at once see the essential core of any problem, and a friendly discussion between him and F. G. Gregory, who was as usual bubbling with ideas, was an intellectual joy to witness.

Richards served as executive editor of *Plant and Soil* and also on the editorial board of the *Journal of Experimental Botany*. Although he never held a teaching post, his influence on younger research workers was very considerable. In his unhurried, quiet, helpful and completely unselfish manner he would stimulate their enthusiasm as well as their critical faculties and bring out the best in all who had contact with him, and many a scientific paper which did not carry his name or even an acknowledgment was the better for his meticulous attention.

The interest in natural history in his parental home found its reflexion in Richards's scientific hobbies. He built his own reflector telescope, made a collection of most of the commoner macro-lepidoptera; a keen photographer, he specialized in stereo-photography, and above all, he enjoyed his mathematical interests: number theory, the Fibonacci series and numerous geometric and algebraic variations he derived therefrom. During his holidays in Wales, Dartmoor and elsewhere, he pursued his archaeological interests, visiting prehistoric sites and collecting artefacts. With his keen eye he even discovered and made a collection of palaeolithic flint tools on the classical fields of Rothamsted. All these hobbies were followed with the same meticulous thoroughness as was displayed in his work, and his students and colleagues were privileged indeed to share in them. When he died at the early age of sixty-three there can have been few people whose retirement would have held greater promise of useful and enjoyable activity.

He will be remembered with the greatest affection by his many friends, students and colleagues, and his wife and two daughters who survive have our sincerest sympathy in their loss.

W. W. SCHWABE

WHEN Dr. Rex Dean died on December 2, 1964, Britain lost an exceptional character.

After he left school, Dean went straight into the Bank of England and worked there for ten years. Here he found time for his artistic interests and revelled in the art galleries and musical opportunities of London. One of his characteristics was a desire for knowledge. Books were good, but better still was the chance of talking to an expert. He was not interested in money, and his restless ambition and enthusiasm found no satisfaction in a banking career. Comparatively late in life, therefore, he began to study medicine at St. Thomas's Hospital, where he qualified in the shortest possible time and took up a house appointment at Addenbrooke's Hospital, Cambridge, in 1943. By this time he was an accomplished pianist with a profound knowledge of the great musical masters past and present. He was also a painter of no mean skill.

Dean at once began to show his devotion to clinical medicine. He loved to examine all his patients himself, never took anything for granted and always saw that everything possible was done for their present and future welfare. He joined the Department of Medicine (later the Department of Experimental Medicine), Cambridge, in 1944 and thus started a career in medical research which he was to pursue for the rest of his life.

Dean went to Germany in 1946 with the Medical Research Council team that set out to investigate the effects of undernutrition on the German population. Here he took an active part in all the studies that were being made, and we quickly began to value his ability, not only as a clinician but also as an administrator. As an investigator he was at first almost a beginner, but he quickly grasped the essentials of organizing a controlled experiment involving a large number of people, and he was a tower of strength throughout the three years we were in Wuppertal. Dean worked very hard, and from the very beginning set high standards for himself and those working under him. His relaxations were painting and music. He delighted in the Bechstein grand piano which was in the 'Herrenzimmer' of the old German house where we lived, and he often went on playing long after everyone else had gone to bed.

The first investigation of which Dean took sole charge was one designed to find out if plant proteins could substitute effectively for milk proteins in the diet of infants and young children. It was possible to do this under controlled conditions in Wuppertal at that time, for the City and even the orphanages were desperately short of milk. He first tried soy bean proteins and at once ran into difficulties over the trypsin inhibitor associated with them, and made numerous journeys to visit experts, manufacturers and others who might help him and at the same time kept the nutritional work going and, even more important, the German staff at the orphanage and the public health authorities solidly behind him. The results of this investigation were published as a *Medical Research Council Special Report*, and on the basis of this work Dean was awarded the Ph.D. (Cambridge) degree.

Dean's success with this investigation made him anxious to apply the results on a large scale where they were clearly needed and likely to be so for some time. His chance came when he was invited by the Medical Research Council to set up a Unit for the study of infantile malnutrition at Kampala. From this he never looked back and, in spite of great difficulties and misunderstandings at times, he gradually built up an organization centred on the small research hospital and laboratories which he himself designed. The money for this was provided, largely through his own persuasive efforts, by the Uganda Government, the World Health Organization and the International Children's Centre in Paris, but he was always supported by the Medical Research Council. Here

Dean was in his element. He explored the possibilities of a number of plant proteins, but never lost sight of the importance of getting at the fundamental biochemistry of kwashiorkor, and his own work and that of his colleagues has thrown a flood of light on the disturbances in enzyme function and amino-acid metabolism which are such a feature of it. Through it all Dean always remained the clinician. He set up the highest standards of diagnosis and investigation, but always put the welfare of his children first. He knew how to deal sympathetically with those in charge of the child, and how to explain to them in the simplest possible way the child's future needs. When Dean first went to Uganda, severe kwashiorkor was quite common, but now it is rarely seen. This is largely due to his work and his influence, and 'Dr. Dean' is a household word among the people living in a wide area around Kampala. On the strength of his work in Wuppertal and Uganda he was elected a Member and later a Fellow of the Royal College of Physicians, honours which he much prized.

Dean was part author with Profs. H. C. Trowell and J. N. P. Davies of a book entitled *Kwashiorkor*, which was published in 1954 and is now the standard work on the subject. He also published many scientific papers describing his observations in Uganda.

At one period of his career Dean travelled a great deal for the World Health Organization, and one of these journeys in 1955 led him to Malaya. There he was asked to see a child in a jungle village suffering from an obscure disease. It was characteristic of Dean to accept such an opportunity to acquire experience and at the same time to be of help, but from this child he contracted an unknown virus infection which led to an ascending paralysis from which he never fully recovered, although some of his finest work was done thereafter. No longer able to take exercise on his feet, he took up swimming to keep himself fit and used to make a habit of this whenever he could afford the time. He remained in full charge of his Unit at Kampala until a few days before his death and, although he had become increasingly aware that his own future was becoming only too short, he continued to make plans enthusiastically for the future of his Unit and his staff.

Dean married in 1931, and is survived by his wife and daughter, who has taken up music as her career. He will be missed by many people throughout the world, but not least perhaps by the unborn babies of Uganda.

E. M. WIDDOWSON  
R. A. McCANCE

## NEWS and VIEWS

### General Physiology in the University of Leicester :

Prof. R. Whittam

DR. R. WHITTAM, who has been appointed to the new chair of general physiology in the University of Leicester, read chemistry at the University of Manchester after service in the Royal Air Force and in 1951 joined the Department of Biochemistry in the University of Sheffield, under Prof. H. A. Krebs, first as a Ph.D. student and later as a Stokes Research Fellow. He worked as a Beit Memorial Research Fellow in the Physiological Laboratory, Cambridge, from 1955 until 1958 under Prof. A. L. Hodgkin and then moved to Oxford, first as a member of the Medical Research Council Unit for Research in Cell Metabolism, and later as a University lecturer in biochemistry. In 1959 he spent 6 months in Prof. D. Nachmansohn's laboratory at Columbia University, New York. His research work has been mainly concerned with the chemistry of physiological functions and especially with those processes which involve the migration of ions across cell membranes. Together with a number of collaborators he has investigated in particular the problem of how the chemical energy of foodstuffs supports such activities as secretion, mechanical contraction and electrical conduction. He has recently published a book *Transport and Diffusion in Red Cells*, one of the monographs sponsored by the Physiological Society. Dr. Whittam will bring valuable experience to the University of Leicester and further strengthen the School of Biology which was recently extended by the creation of a Department of Biochemistry (Prof. H. L. Kornberg) and a Department of Genetics (Prof. R. M. Pritchard).

### Biochemistry in the University of Newcastle upon Tyne :

Prof. Kenneth Burton

DR. KENNETH BURTON, who is at present on the staff of the Medical Research Council's Cell Metabolism Research Unit in the Department of Biochemistry, University of Oxford, has been appointed to the newly-created chair of biochemistry in the University of Newcastle upon Tyne. Dr. Burton, a scholar of King's College, Cambridge, graduated in 1946. After a period of research in Cambridge he moved to Sheffield and later spent two years in the Department of Biochemistry in the University of

Chicago. His especial interest lies in the field of molecular biology, particularly the biochemistry of nucleic acids. The establishment of a new chair in biochemistry is part of a plan of expansion in biological sciences at Newcastle. It is expected that the teaching of biochemistry as a separate subject will begin in October 1966.

### The Oersted Medal :

Prof. Philip Morrison

PROF. PHILIP MORRISON, of Cornell University, has been awarded the twenty-ninth annual medal conferred by the American Association of Physics Teachers. Prof. Morrison has contributed many research papers, and collaborated with H. Bethe in the production of a well-known text-book on nuclear theory. His teaching experience ranges "from kindergarten to postgraduate institutes". He originated and directed a course in physics for non-science students at Cornell, and he has pioneered the teaching of science in the elementary school, especially light, mechanics, and applied mathematics. He has prepared a book on elementary science education, but is at present working in the Massachusetts Institute of Technology on a quantum mechanics text-book for first-year university students. Prof. Morrison has been a faculty member of Cornell University since 1946, and a full professor since 1956; he has visited, and taught in, London, Israel, India and Japan.

### Professional Civil Servants

IN commenting on the debate in the House of Lords on December 2, 1964, in which several speakers referred to the serious shortage of engineers, Mr. J. Lyons, writing in the February issue of *State Science*, the journal of the Institution of Professional Civil Servants, continues the Institution's criticism of the Government's failure to provide satisfactory conditions of service for its own professional staff. By the end of 1965 the pay research report on the Works Group should be available and negotiations on the pay of engineers and other professional staff in the Civil Service should commence. By that time, Mr. Lyons concludes, the Government should demonstrate very clearly, by the way it improves the salaries and status of its own professional staff, the importance it attaches to raising the status of technology and technologists throughout Britain.

## Student Numbers at U.K. Colleges of Advanced Technology

IN a written answer in the House of Commons on February 9, the Secretary of State for Education and Science, Mr. A. Crosland, stated that of the 13,811 full-time and sandwich students who had enrolled at the ten colleges of advanced technology in October 1964, 10,192 were in technology, 2,461 in science, 824 in social studies, and 334 in liberal studies. For October 1963 the corresponding figures were: 11,557, 8,925, 1,862, 559, and 211; and for October 1962: 10,089, 8,052, 1,500, 357, and 180. Of the 135,186 full-time university students (undergraduate and postgraduate) enrolled in October 1964, 19,964 were in technology, 35,799 in science and mathematics, 19,794 in medicine, dentistry, veterinary science, agriculture and forestry, and 17,671 in social studies. For October 1963 the corresponding figures were: 124,002, 18,101, 33,212, 19,042, and 15,405; and for October 1962: 116,610, 16,652, 30,791, 19,230, and 13,273. In a further written answer on February 11, Mr. Crosland added that in October 1964 universities in Great Britain, excluding Oxford and Cambridge, planned to admit 5,610 students to study technology, but 420 fewer were admitted.

## Transport Planning

IN reply to a question in the House of Commons on February 8, the Minister of Transport, Mr. T. Fraser, announced that Lord Hinton was temporarily to join his Ministry as a special adviser on transport planning. He would be responsible for enquiring into the means whereby, and the extent to which, the transport of goods and passengers in Britain could best be co-ordinated and developed in the national interest. The study, which was expected to be completed before the end of the year, would, in particular, examine: (1) the pattern of long-distance transport services likely to be required in the future, with particular reference to the co-ordination of investment policies for highways and railways; (2) the methods of achieving a properly co-ordinated use of the main trunk route transport systems, and especially the right balance between the use of road and rail; (3) how operational co-ordination could be improved between different forms of transport. Mr. Fraser said he was also appointing a small Transport Advisory Council, with himself as chairman, and with Lord Hinton as a member, to assist him on transport policy matters generally. The other members would be: Prof. A. Day, Lord Holford, Prof. E. F. Jackson, Alderman H. Walton, Messrs. J. F. H. Davies, W. J. P. Weber and E. G. Whitaker. In answer to further questions as to the functions of this Council, Mr. Fraser said that it would consider the whole question of the implementation of the Buchanan Report and the very large problems connected with intra-conurbation transport. While admitting that the co-ordination of air services did not come under the Ministry of Transport, he wanted Lord Hinton to advise on the co-ordination of rail, air, road and sea transport so that a complete picture could be obtained for determining the best way to co-ordinate the whole of Britain's internal transport services.

## The Atomic Energy Authority: Trading Fund

IN a written answer in the House of Commons on February 9, the Minister of Technology, Mr. F. Cousins, announced that from the beginning of the next financial year the commercial operations of the Atomic Energy Authority would be separated from the Authority's other activities, which are financed directly from the Atomic Energy Vote, and organized in a Trading Fund. These production activities had grown substantially in recent years, particularly the manufacture of fuel elements for sale to electricity generating authorities and for export, and sales for the next few years were likely to be: reactor fuel elements, £20 million; electricity, £7 million; radio-

active isotopes, £2 million. No change was involved in the organization and responsibilities of the Authority, nor was legislation required. The new arrangements would provide a suitable financial basis for the Authority's fuel element business, based on the Springfields plant, and would also cover the reactors at Calder Hall and Chapelcross, and the Radiochemical Centre at Amersham. The diffusion plant for the production of uranium-235 at Capenhurst and the plutonium separation plant at Windscale would not initially be brought within the Fund, but their inclusion would be considered when appropriate. The former was running at a low level of output pending decisions on the production of uranium-235 for such purposes, and trading activities at Windscale were relatively small.

The operations of the Fund would be subject to examination and audit by the Comptroller and Auditor General, and its establishment would have no effect on Defence costs. A target surplus had been agreed for the Fund, after meeting interest on capital, depreciation and other normal charges, including research and development costs, which envisaged earnings over five years to yield a surplus of £3.9 million. The Fund would retain depreciation provisions and trading surplus and would be enabled to build up its own reserves to meet contingencies and normal capital investment requirements. Its initial capital would suffice to cover the book values of both the fixed and working capital of the plants concerned, at present estimated at about £37 million, and the Exchequer would receive from the Fund interest on the initial capital and also a contribution in lieu of income tax where tax would be payable under the normal scales. Introduction of the Trading Fund would increase the existing net Atomic Energy Vote by eliminating receipts from trading operations, but this increase would be partly offset by an increase in the Exchequer Extra Receipts of interest, and the Exchequer would not in future have to provide for the Authority's capital needs that amount which could be met from reserves.

## Atomic Energy Board in South Africa

THE 3-MeV Van de Graaff particle accelerator is now fully operational at Pelindaba, the National Nuclear Research Centre. Costing R175,000, the accelerator is housed in its own building on the Pelindaba site, and since its commissioning in the past few weeks it has begun to play a significant part in the Atomic Energy Board's research activities. Its completion has preceded that of the Board's research reactor, *Safari I*, which will 'go critical' later this year. While there are two more powerful accelerators already operating in South Africa—the 16-MeV cyclotron at the Council for Scientific and Industrial Research and the 5.5-MeV Van de Graaff accelerator at the Southern Universities' Nuclear Institute—the Pelindaba machine possesses certain advantages for the specific research on which it will be used. First, it provides a more stable particle beam than the cyclotron, and secondly, it has a higher beam intensity than its counterpart at the Southern Universities' Nuclear Institute. It is also a pulsed accelerator enabling it to produce neutrons in short bursts and so permit time-of-flight experiments which are especially useful in fast neutron physics studies. The Pelindaba equipment will be available to universities for pure fundamental physics research.

## Photonuclear Reactions Series

No. 10 in the *Bibliographical Series* of publications of the International Atomic Energy Agency deals with photonuclear reactions—the interactions of electromagnetic waves with nuclei. The most important aspects of the theoretical and experimental investigations of the photo-disintegration of light are covered, as well as intermediate and heavy nuclei, photofission, electrodisintegration, and the absorption and scattering of protons. A special chapter is devoted to the photoproduction of elementary

particles. There are 2,254 references to articles in English, French, Russian, German, Italian, Japanese and other languages, published during January 1948–August 1963. The authors, English title and periodical reference are given, together with an abstract in English when possible, and the bibliographical sources used were *Nuclear Science Abstracts*, *Referativnyi Zhurnal Fizika*, *Physics Abstracts*, and journals and reports submitted by member States of the Agency. The references are classified into fifteen categories: general theory; photodisintegration of the deuteron, of tritium and helium, of light nuclei, of intermediate nuclei, and of heavy nuclei; photofission; electrodisintegration; photoproduction of mesons; books and survey articles; bremsstrahlung and X-rays; resonant scattering; elastic and inelastic scattering; absorption of photons; and miscellaneous. A comprehensive author index and a subject index complete an extremely valuable bibliography. The print, though small, is extremely clear and sharp, and the presentation of the text is in many respects an improvement on that of the original sources.

### Galileo Galilei

GALILEO GALILEI was born on February 15, 1564, and to celebrate the quadricentennial of his birth, Lehigh University, Bethlehem, Pennsylvania, held an exhibition, during October 1–December 31, 1964, of books and manuscripts by, and relating to, Galileo. A descriptive brochure has been prepared by J. D. Mack, the librarian of the University (*Brochure on an Exhibition of Books and Manuscripts by and Relating to Galileo Galilei upon the Quadricentennial of his Birth, 1564–1964*. Pp. 32. Bethlehem, Pennsylvania: Lehigh University Library, 1964). Galileo's father was a Florentine cloth merchant who was adept at drawing and who wrote extensively on music. Galileo was sent by his father to study medicine at the University of Pisa, but Galileo's main interest was in mathematics, and in 1589 he was appointed professor of mathematics at Pisa. He later moved to the University of Padua. In his comments on the 29 exhibits, Mr. Mack traces Galileo's contributions to mechanics, his astronomical observations and his arguments in favour of the Copernican cosmology, which led him into conflict with the Roman Catholic Church and finally to the judgment of the Inquisition. In addition to the works of Galileo the exhibition also contained 17 works more or less directly related to his life and writing, including a copy of Aristotle's treatise *On the Heavens*; a first edition of the *Dialogue on Music* by Galileo's father; the first English translation of Galileo's *Dialogue Concerning the Two Chief World Systems* by Thomas Salisbury—a very rare edition of 1661; and Newton's *Principia*. Mr. Mack prefaces his comments on the exhibits by a brief analysis and appreciation of Galileo's contributions to science. He emphasizes that throughout his career Galileo argued that only by means of mathematics and experiment was science possible and that their introduction made it impossible for science to remain static. Galileo first achieved a European reputation through his use of the telescope, and this is indicative of the dependence of Galileo's science on technology and of his view that science should be useful.

### National Lending Library for Science and Technology

A REPRINTED brochure describing the National Lending Library for Science and Technology, issued by the Department of Scientific and Industrial Research in August 1963, has now received further slight amendment. In November 1964 the Library was receiving 6,800 requests for loans weekly, of which 81 per cent were met from its own stock, about 8 per cent being passed to the Science Museum Library. Telex requests amount to about 250 per week, and photocopying requests to 550. Chemists (28.6 per cent), engineers (21.5 per cent) and physicists (11.9 per cent) are the principal borrowers, engineering

(22 per cent), chemistry (19 per cent), physics (15 per cent), biology (13 per cent) and applied chemistry (8 per cent) being the chief subjects of requests for loans. Approved borrowers now number about 2,240, and industrial firms are prominent among institutional users, accounting for just under half the weekly requests. The translating service provides current cover-to-cover translations of 16 periodicals, besides about 300 translations of articles, at a cost of £150,000 a year net or £50,000 gross. Expenditure on literature is at present about £146,000 a year, and 20,500 current titles of serial publications are being received from more than 100 centres. Of the 122 non-industrial staff, 27 are scientific and experimental grades. After English (72 per cent), German (9.8 per cent) and French (4.6 per cent) are the most frequent languages of requests, and educational establishments (29 per cent) and Government departments and establishments (12 per cent) follow private firms (44 per cent) in the proportion of requests for loans. Besides the course for postgraduate research students in January 1964, two courses were run for university library staff in April and July 1964, and a third course is being arranged for Easter 1965. Nearly 15,000 books in the English language and about 24,000 in the Russian language are held, the monthly intake being about 250 and 400, respectively, and microfilms of translations and reports equivalent to 96,000 volumes are also held, but this intake is expected to be replaced by microfiche.

### Institute of Biology

ON January 14, the Institute of Biology celebrated its fifteenth anniversary by a dinner at the Imperial College of Science and Technology. After the dinner, Prof. G. E. Blackburn, retiring president, presented to his successor, Prof. O. E. Lowenstein, a silver-gilt badge of office to be worn by future presidents. At the preceding annual general meeting, the honorary secretary, Dr. L. Broadbent, had reported that membership of the Institute had reached 3,550 and that with a continuing growth at its present rate membership would reach 4,000 in one year's time: this would be about half the number of qualified biologists employed in the United Kingdom. The Institute has just published regulations for the award of M.I.Biol. by examination, and part-time courses are expected to start at some of the larger technical colleges in September 1965. The ferment in biological education in schools, technical colleges and universities and the Institute's own increasing responsibility for training in applied biology have led to the appointing of an education officer, Mr. L. J. J. Brandon, who will commence work in April 1965.

### Symposium on Crustacea, Cochin

AN international Symposium on Crustacea, organized by the Marine Biological Association of India in conjunction with the University of Kerala, was held in the Oceanographic Laboratory, University of Kerala, Cochin-Ernakulam, during January 12–15, 1965. The symposium was under the chairmanship of Dr. S. Jones, president of the Association and head of the Central Marine Fisheries Institute, Mandapam Camp, South India. More than 100 participants registered, including a number from Europe and the United States. The symposium was inaugurated by Prof. Samuel Mathai, vice-chancellor of the University of Kerala, Trivandrum, and the accompanying exhibition on biology and fishery of crustacea was opened by Mr. Per Sandven, director of the Indo-Norwegian Fishery Project, Ernakulam. Abstracts of 144 papers were received before the meeting. Only those of authors present were read and discussed, these constituting a very full programme for the three days set aside for the reading of papers. Many aspects of biology, ecology and fishery for crustacea in various parts of the world were discussed. The progress of work on

Indian species of importance as food or as a cause of marine deterioration was fully covered. An invited lecture by an expert from the United States or the United Kingdom was given on each of the four evenings of the meeting. Delegates are indebted to the Marine Biological Association of India, the director, Indo-Norwegian Project, the University Department of Marine Biology and Oceanography, and the Seafood Canners and Freezers Association of India for hospitality during the meeting. It is expected that the *Proceedings* of the symposium will be published towards the end of 1965. Enquiries regarding this publication should be addressed to the Managing Editor, Marine Biological Association of India, Marine Fisheries P.O., Ramanathapuram District, South India.

#### University News:

#### Leeds

THE University of Leeds, for many years ranked among the bigger provincial universities, has now become the second largest of the 'civic' universities in England, outside London. In 1938-39 the total of full-time students was 1,757; in 1963-64 it was 6,233. Under development plans now in hand, the student population is expected to reach 8,300 in 1967, eventually to exceed 10,000. In November 1964 the University of Leeds published a documented and well-illustrated brochure entitled *University Studies in Applied Science and Technology*, being in fact an introduction to the degree courses in the Faculty of Technology, now so much in the forefront of higher educational and political planning (Pp. 88. Leeds: The University, 1964). While the academic side of the various faculties of learning in this University is by no means subordinated to present-day demands for trained technologists as such, the emphasis in this excellent guide to what is offered to "parent, potential student or teacher—to the schemes of study in applied science and technology at the University of Leeds" (to quote from the Vice-chancellor's foreword), is on practical application of the subjects of study available. These include agriculture; applied mineral sciences; ceramics; colour chemistry and dyeing; chemical, civil, electrical and mechanical engineering; food science; fuel science; leather science; metallurgy; and textile industries. Full information is given on degree schemes, careers, postgraduate courses and research in the several subjects of study; apart from this, the illustrations of the University precinct and environment, of its buildings, and particularly of its many finely designed and equipped laboratories, are convincing enough to attract widespread attention from those to whom this official publication was meant to appeal. "The University, only one mile from the city centre, and yet within such easy reach of the moors and dales, is thus fortunate in being able to offer its students all the attractions of a large modern city, and at the same time unique opportunities to escape from the fumes and noise of urban life to the beauty and peace of unspoilt rural surroundings." Those who know the University to-day would certainly agree that this, compared with less fortunate centres of learning in Britain, is no over-statement.

#### Mullard Research Fellowships

MULLARD RESEARCH LABORATORIES have established a limited number of research fellowships (to be awarded on a basis of personal invitation) to enable visiting scientists to spend a period of about one year at the Mullard Laboratories, Redhill, Surrey. The Fellowships will enable scientists engaged in academic, government or industrial laboratories to work with well-established teams in the Research Laboratories. Joining a 'ready made' research team, it is hoped, will facilitate individual contributions with the minimum of non-productive work. Fellows will normally have had experience in a sphere in which the Mullard Laboratories are active and will come from Britain and overseas. Stipends "appropriate to the status and seniority" of the Fellows will be paid.

#### Research Fellowships in Fisheries Science

THE Fisheries Division of the Irish Department of Lands, in co-operation with the constituent Colleges of the National University of Ireland, Trinity College, Dublin, Queen's University, Belfast, the Irish Sugar Co., Ltd., and the Institute for Industrial Research and Standards, Dublin, is to award a research fellowship in fisheries science, tenable for at least three years. The fellowship will be awarded to a man or woman with an honours degree, preferably in biology, for full-time research into water purity and the various conditions affecting fishery productivity in selected Irish rivers. Further information can be obtained from the Secretary, Department of Lands, Fisheries Division, 3 Cathal Brugha Street, Dublin 1.

#### Announcements

DR. D. M. KEMP has been appointed chief chemist of the Atomic Energy Board of South Africa as from January 1. Dr. Kemp joined the Board in 1962, and since the middle of that year has headed the Chemistry Division. Dr. J. W. L. de Villiers has been appointed senior principal research officer. Dr. de Villiers joined the Reactor Engineering Division of the Board in October 1959, and spent more than two years on extensive training at several overseas institutions, notably the Argonne National Laboratory in the United States.

DR. F. BLOCH, professor of physics at Stanford University, became president of the American Physical Society on January 30. Dr. Bloch succeeded Dr. R. F. Bacher, Provost of the California Institute of Technology. Dr. J. Wheeler, of Princeton University, became vice-president and Dr. C. H. Townes, Provost of the Massachusetts Institute of Technology, became vice-president-elect of the Society.

THE Helen B. Warner Prize of the American Astronomical Society has been awarded to Prof. M. Schmidt, professor of astronomy at the California Institute of Technology, for his spectroscopic studies of radio galaxies and quasi-stellar radio sources.

THE Smithsonian Astrophysical Observatory, Cambridge, Massachusetts, has announced that it has been requested by the International Union of Geodesy and Geophysics and the International Committee on Space Research to establish and operate a Central Bureau for Satellite Geodesy.

THE seventy-first annual conference of the Museums Association will be held in Dublin during June 21-26. Further information can be obtained from the Secretary, Museums Association, 87 Charlotte Street, London, W.1.

A JOINT conference of the Aeronautical and Technical Translation Group of Aslib will be held at the College of Aeronautics, Cranfield, during April 1-3. Further information can be obtained from the conference secretary, Mr. E. J. MacAdam, 74 Stancliffe Road, Bedford.

A CONFERENCE on "The Effects of Sunlight in Buildings, with Special Reference to the Visual Effects", arranged under the International Commission on Illumination, will be held at the University of Newcastle upon Tyne during April 5-9. The programme will include papers and discussions on: psychophysical aspects of the admission and exclusion of sunlight in buildings—visual and thermal comfort; physics of sunlight and the radiation distribution of the clear sky; sun position diagrams and lighting calculations; design of sun control devices; design criteria for sunlight in buildings. Further information and forms of registration can be obtained from Mr. J. Longmore, Building Research Station, Garston, Watford, Hertfordshire.

## SCIENTIFIC RESEARCH IN AUSTRALIA

THE sixteenth annual report of the Commonwealth of Australia Scientific and Industrial Research Organization\*, covering the year ending June 30, 1964, includes lists of published papers and of the members of the Advisory Council, State Committees and staff. Of the total income of £14.87 million, £10.7 million was by Treasury appropriation, with a further £583,910 for capital works and £2.4 million from the Wool Research Trust Fund. Of the £10.8 million expended on investigations, 36.6 per cent was on agricultural research, 9.7 per cent on processing of agricultural products, 11.6 per cent on physical research of industrial interest, 8.1 per cent on chemical research of industrial interest, 7.3 per cent on general physical research, 6.8 per cent on processing, recovery and use of minerals and coal, 4.5 per cent on general industrial research, 2.8 per cent on fisheries and 5.5 per cent on research services. The shortage of laboratory accommodation remained acute.

Among the research developments emphasized in the survey are the studies by the Controlled Environment Research Laboratory in the Division of Plant Industry. These were concerned with the distributions of temperature, humidity and solar radiation in the canopy of two contrasting plant communities, a wheat field and a pine forest, and with the corresponding distribution of evaporation sources and the movement of sensible heat. Recent work at Katherine has shown that Townsville lucerne pastures without the perennial grass are of greater feeding value in the dry season than grass/Townsville lucerne pastures, and the results point towards more productive grazing systems for beef cattle in the far north. Research on the nutrition of tropical legumes has provided information which will be invaluable in establishing and managing them in pastures and has also shown that their responses to fertilizers often differ from those of temperate legumes. Studies on the Northern Tablelands have indicated that, although there are very broad relations between the appearance of the soil and its general fertility status, the pattern of the relationship varies with different elements.

Genetic and clinical work on the enteric bacillus *Escherichia coli* indicates at least five ways in which a bacterium, and probably any other organism, can become resistant to a poison.

The tenth survey of land resources in Papua and New Guinea was completed in 1963, and about one-sixth of the area of these territories has now been surveyed. Generally surveys have revealed the existence of larger areas with a potential for development than was expected. Studies of the drying of grapes used mainly for production of sultanas or raisins showed that the rate of drying is determined by the wax constituents, which control the loss of water, and the rate can be increased by a brief immersion of the grapes in an emulsion of oil and potassium carbonate before drying. A systematic investigation being carried out on the ensiling characteristics of tropical pasture species should facilitate development of more suitable ensilage techniques and even indicate features to the plant breeder which could be introduced into otherwise unsuitable strains.

Field and laboratory studies associated with more than fifty failures of earth dams have revealed two main patterns, apart from seepage losses through the floor of the dam; chemical studies on the water and the clay fraction of soils from dams which failed when it was first filled with water showed that these 'sus-

ceptible' soils are dominated by monovalent cations, such as sodium, in the exchange complex of the clay. Research programmes are also in progress which are aimed at evaluating the pedological and terrain systems of classification as a basis for obtaining and recording such data for engineering purposes.

The report points out that, so far, the Animal Health Laboratory at Parkville has succeeded in isolating viruses of some six bovine diseases from Australian livestock which cause economic losses in herds, especially in younger animals through their effects on the brain and associated nervous tissues, the respiratory tract, the genital tract and the intestines. Some of the results of the investigations which have established the critical importance of the cobalt-containing complex vitamin B<sub>12</sub> and of a continuous supply of cobalt to protect sheep against *phalaris* staggers are reviewed. Other investigations have indicated that the supply of protein available for digestion and absorption in the small intestine is an important nutritional factor limiting the rate of growth of wool—its content of *S*-amino-acids being particularly important. Cystine, labelled with carbon-14 or sulphur-35, is being used to measure the rate of growth of length of wool fibres on experimental sheep, and besides investigations into contagious bovine pleuropneumonia, there is a concurrent programme of fundamental research into the biology of the pleuropneumonia organism and related organisms. Studies of the inheritance of tick resistance in cattle indicate that tick resistance is highly heritable and it should be possible to breed for this character.

Studies on the ecology of *Sirex noctilio*, a serious pest of *Pinus radiata* in Australia, and of two parasites *Ibalia leucospoides* and *Rhyssa*, now well established in Tasmania, are in progress and, although no dramatic control by these parasites is expected, the *Sirex* population should be reduced. The main features of the distribution of blue-fin tuna in Australian waters have now been determined, and factors influencing reproduction in the rabbit are being studied in climatic and pastoral conditions from sub-tropical through semi-arid to sub-alpine.

A special Fabry-Pérot interferometer has been constructed to measure the width of the green oxygen line in the high atmosphere and its variations from night to night. The electron microscope and a 'field-ion' microscope are being used in investigations of the creep of metals and have detected cavities at grain boundaries at a very early stage of development. Proton magnetic resonance spectrometry has now shown conclusively that dimethyl aluminium chloride exists as such in solution in ether. Other investigations have been concerned with the chemical properties of water at very high pressures, and the structure of casein micelles; a new chromatographic procedure for determining lanthionine, and a radiochemical method for thiol analysis, have been used to evaluate the relative roles of these groups in the setting process of wool. A new enzyme, protein disulphide reductase, which is involved in the reactivation of triode phosphate dehydrogenase, has been identified, and it would seem that it may be partly responsible for the Pasteur effect in intact plant tissue. The polyphenols in the leaves of the *Eucalyptus* genus are being surveyed and most of the genus has been examined. A new type of high-intensity atomic spectral lamp has been developed and considerable progress has been made towards deriving a mathematical model to account for the stages of breakage of selected size ranges in ball-grinding. An investigation of load distribution in wooden floors has indicated that nailing floors to joists and joints to bearers has little effect. Results with a solar air-heater and rockpile have

\* Australia: Commonwealth Scientific and Industrial Research Organization. Sixteenth Annual Report, 1963-64. Pp. 187. (Melbourne: Commonwealth Scientific and Industrial Research Organization, 1964.)

led to the installation of a full-scale prototype air-heater and thermal storage system to heat part of a laboratory. Studies of molybdenum disulphide have demonstrated its outstanding adherence to metal surfaces. A new

machine has been designed for shelling peas, while new fibre-board containers have been designed for transporting apples and pears. A prototype machine for the continuous dyeing of wool slubbing has been constructed.

## THE RESEARCH COUNCIL OF ALBERTA

**T**HE forty-fourth annual report of the Research Council of Alberta\*, which covers the year 1963, includes the usual reports of branches and divisions, and lists of publications (1959-63), and members of the technical and other advisory committees. About one-quarter of the total effort is now devoted to mapping and classifying natural resources, about 10 per cent to investigations undertaken jointly with other Government agencies including the highway research, hail studies and watershed research programmes.

Almost half the total activity of the Council is devoted to long-range research programmes directly or indirectly related to the natural resources of the Province. In recent years, forest projects of direct industrial significance have become more prominent in the Council's programme. Several of the longer-range studies have reached a stage when they are leading to developments of commercial significance. Particular reference is made in this connexion to the development of a process for producing iron from the low-grade ores in the Peace River area, to work on the pipeline transport of solids, and to the development of several new products from coal.

In the Coal Division, interest during the year continued to centre on the study of the 'paste-slug' technique for pipeline transport of granular solids, while work on coal chemicals was chiefly directed to investigations of humic acids and their application.

The Petroleum Division is nearing the completion of a massive analysis, based on data from several thousand wells, of the regional distribution of oil, gas and water in the various formations of the Alberta sedimentary basin. Several possible means of transporting sulphur by pipeline were explored during the year, while investigations of the kinetics of hydrocarbon reactions were concerned with the decomposition of ethylene oxide and of ethylene imine, under both photochemical and thermal activation. The technique of electron-spin resonance spectroscopy is being applied to questions relating to coal and carbon structure in the in-

vestigation of certain charge-transfer complexes which are similar in spectral behaviour to coals and chars. Another investigation involved a series of 10 methylated anthra-semiquinones, and demonstrated the stearic hindrance of a methyl group in the one position in anthraquinone.

In the Earth sciences, a regional survey of the ground water resources of the Peace River block was completed, and pilot plant investigations were continued into a process for producing high-grade iron powders from the iron deposits in the Clear Hills. An evaluation of the ground water resources of some 17,000 square miles of East Central Alberta was published. Stratigraphical studies had their main emphasis on the Cretaceous rocks of Alberta, but research is also in progress on Precambrian, Mississippian, Tertiary and Pleistocene strata. A detailed field study was made of the Marmot Creek Basin near Kananaskis, west of Calgary, and, during soil surveys, the presence of a permanent icepan in organic soils in parts of Alberta was noticed; the chemical forms of sulphur occurring in Alberta soils are also being studied.

Under the hail studies programme, analysis of small-scale pressure patterns over the project area indicates an interesting relation between the small high-pressure areas and the rainfall. Physical research into problems relating to highway design, undertaken within a co-operative programme sponsored by the Department of Highways, the Department of Civil Engineering of the University of Alberta and the Research Council, included investigations into the properties and behaviour of soils and paving materials, the structural design and evaluation of pavements and problems in the hydraulics of highway bridges and related structures. Work continued on the problem of scour around bridge foundations in alluvial streams. Industrial and engineering services included investigations aimed at the development of techniques for producing foamed asphalt and foamed sulphur. Studies of the ten-year biological cycle have been primarily devoted to the ecology and population dynamics of the Snowshoe hare which, as the dominant herbivore and basic prey species, holds the key to the cycle.

## INTERNATIONAL COLLABORATION IN PULP AND PAPER PRODUCTION

**F**ROM time to time, the Food and Agriculture Organization of the United Nations, the headquarters of which are in the Via delle Terme di Caracalla, Rome, in collaboration with Unesco or a similar body, organizes elaborate conferences having the objective of exploring ways and means by which the fibrous natural resources of developing countries can be used to the best advantage to produce pulp and paper. Normally the regional areas covered by a symposium are quite large. Thus, in 1954 and 1959 Latin America and South-east Asia and the Far East were covered, respectively; and in 1965 Africa will come under review. A similar regional symposium, but on a rather smaller scale, was also held in Beirut, Lebanon, in December 1962, having as its subject pulp and paper research and technology in the Middle East and North Africa\*. On this occasion the Food and Agriculture

Organization and Unesco acted jointly. The papers read were published by Unesco several months ago (somewhat belatedly, one feels).

These symposia follow a generally similar pattern, the usual procedure being to receive papers of three different types. First are those prepared by the Food and Agriculture Organization Secretariat in Rome; they usually summarize the position in the region as a whole and do so mainly from an economic angle. Official representatives of the individual countries in the region then summarize the present position in their respective countries, and their hopes and plans for the future. Finally, papers also come from invited consultants, who present appropriate case studies or specific technical papers of relevant interest. Ample opportunity is available for discussion of the papers presented, and although this was used to the fullest advantage in the present example in Beirut, and proved extremely valuable, the discussions are unfortunately not reproduced in the published volume.

\* *Proceedings of the UNESCO/FAO Regional Symposium on Pulp and Paper Research and Technology in the Middle East and North Africa, 10-14 December, 1962, Beirut, Lebanon.* Pp. ix+479. (Cairo: Unesco Middle East Science Co-operation Office, 1963.).

An element of incompleteness also arises, partly from the strange geographical frontiers imposed by the organization of these conferences, and partly by the fact that some nations in the region did not participate. Ten nations were directly represented, but countries in the area not directly represented were: Algeria, Afghanistan, Cyprus, Israel, Saudi Arabia, Somalia, Sudan and Yemen.

Specialized papers presented dealt with eucalyptus (San-  
yer); poplar (Bersano); bagasse (Atchison); straw (Muller);  
reeds (Chivu); esparto (Grant); and cotton linters (Howell).

The published version of these papers provides, therefore, authoritative information on a wide variety of specialized aspects of the utilization of fibrous materials. Experience based on the Latin America and Tokyo symposia has demonstrated their value in initiating pulp and paper projects in the region concerned; and the Beirut symposium as recorded in this volume is a further example of the great value of this little-publicized activity sponsored indirectly by the United Nations Organization.

## ART AND SCIENCE OF PACKAGING

THE opening of the new engineering research buildings of the Printing, Packaging and Allied Trades Research Association ('Patra') at its headquarters at Leatherhead, Surrey, on November 4, 1964, directed renewed attention to the important work of this progressive organization. The Printing Industry Research Association, as it was first called, was formed as the result of a lecture, "Application of Science to Printing", given by Dr. G. L. Riddell in the Stationers' Hall, London, on February 8, 1929. A meeting of printing trade organizations was convened which decided to set up "a technical research bureau for the pooling of technical information and to conduct scientific investigation of technical problems". The Stationers' Company at first provided free accommodation, but in 1932 the Association moved to St. Bride's Institute. Laboratory facilities were at this time provided mainly by the London School of Printing (London County Council). By 1936 the Association was renamed the Printing and Allied Trades Research Association and became a grant-aided research unit; it was then moved to premises in Robin Hood Court, off Fleet Street, London. In 1941 these premises were completely destroyed during one of the major fire raids on London, but with generous help from several member firms the Association was re-housed in temporary accommodation in various parts of London and the Home Counties, and so its work continued. By 1942 the packaging problem of service equipment badly damaged on arrival in the Middle East and Far East combat areas had arisen, and with the co-operation of the Department of Scientific and Industrial Research, manufacturers and users of packages, and with an increased grant, the Packaging Division was formed in 1943. This expansion virtually doubled the Association's income, and thus the foundations of the larger organization, as we now know it, were laid and its future was fully secured. Leatherhead has for many years been

a favoured locality for research associations sponsored by industry; this Association moved into new laboratories there in 1948. But within ten years enlarged premises were required and a new wing was added (opened in 1959) to accommodate the Packaging Division. The latest extension, built in 1963 to house the new engineering research buildings, brings the total floor area available at this centre to 42,000 square feet. This growth record in 35 years is one of which the Association may be justly proud. Apart from fundamental research projects based on problems in both printing and packaging techniques, 'Patra' has established some important routine day-to-day technical services, among which are printing enquiries, critical appraisals, machine testing, air-conditioning, high-speed camera service, package testing and advisory service, library, abstracting and translation facilities.

The work of the Association, particularly in the modern field of packaging, has been quite outstanding, although perhaps not as well known as it should be. In this connexion, the division concerned "... assesses products for packaging, recommends methods, materials and containers, tells where to obtain supplies, advises on specifications, tests materials or packs, indicates the standard of package performance and guards against over-packaging by ensuring economic pack design". The package testing laboratory is fully equipped for what in other industries are generally known as 'accelerated breakdown or weathering tests'; both mechanical and climatic hazards that a package may meet in transit can be simulated in a variety of apparatus and specially constructed environments; the scope includes tests applicable to standards of packages and packaging materials recommended in British and American Society for Testing Materials Standards, and in United States and British Government specifications.

## GALACTIC FLARES AND QUASI-STEELAR RADIO SOURCES

By PROF. P. A. STURROCK

Institute for Plasma Research, Stanford University, Stanford, California

AT the present time there is considerable interest in explosions which occur in objects of galactic dimensions. Oort<sup>1</sup> has suggested that such an explosion has occurred in the nucleus of our own Galaxy, and there is convincing evidence of such explosions in certain galaxies<sup>2</sup> which are strong radio emitters, and also in the quasi-stellar objects associated with certain very strong radio sources<sup>3</sup>. In such an explosion, a great quantity of energy is suddenly released in the form of relativistic electrons (which produce radio and optical synchrotron radiation), kinetic energy of ejected gas clouds, and possibly other forms. This energy can be so large that it is at present believed that, for the very strong radio sources at least, it must be derived from gravitational energy<sup>4,5</sup>. The mechanism for release of gravitational energy which has been mostly widely investigated is that of 'gravitational

collapse'<sup>6-8</sup>. However, this theory does not yet give a convincing interpretation of the phenomena it sets out to explain. Gravitational collapse is a runaway process, whereas there is evidence that explosions can recur<sup>9</sup>, indicating that one needs an instability. Moreover, the complicated theories of gravitational collapse have not been integrated into a larger theory showing how the initial conditions of the theory come about, and how the theoretical consequences lead to the observed characteristics of exploding galactic objects—such as strong radio emission. This suggests that alternative processes should be sought for the release of gravitational energy, and it is the purpose of this article to propose one.

Data concerning galactic explosions suggested the following requirements: (1) it should be possible for the mechanism to occur over a wide range of energy; (2) the

mechanism should involve the gradual accumulation of energy and its sudden release; (3) the explosion should be such as to convert a large fraction of the released energy into high-energy particles and mass-motion; (4) it should be possible for the mechanism to repeat itself.

These requirements of a theory of galactic explosions are also requirements of a theory of solar flares<sup>10</sup>. Further considerations show that there is indeed a strong similarity between these two phenomena, which prompts one to enquire whether the mechanism of solar flares might occur on a galactic scale. A preliminary investigation indicates that this is indeed possible, leading to the view that the galactic phenomena referred to may prove to be 'galactic flares'.

Until recently, it was generally believed that the energy released in a solar flare is stored entirely in magnetic form<sup>11</sup>. This point of view would discourage an attempt at identifying galactic explosions as flares. However, a recent investigation of the flare problem by Dr. B. Coppi and myself<sup>12</sup> has led to the conclusion that the energy released in a solar flare is stored partly in magnetic and partly in gravitational form. This new interpretation of solar flares provides strong encouragement for investigating the possible occurrence of galactic flares.

The pre-flare state of a solar flare consists of a mass of gas supported against gravity by a compressed magnetic field. The Coppi resistive instability<sup>13</sup> permits relative motion of the plasma and field, when a certain criterion is satisfied, so that the gas falls and the field expands upwards; this process releases gravitational and magnetic energy in the form of Joule heating, particle acceleration, and kinetic energy of mass motion. A large fraction of the energy goes into Joule heating; a substantial fraction into mass motion; and a fraction above 1 per cent into particle acceleration. This is probably the most efficient mechanism in Nature for converting gravitational energy into relativistic-particle energy.

An analogous pre-flare state on a galactic scale would comprise a large mass of gas which is prevented from collapsing by the pressure of a trapped magnetic field. It is desirable to have a non-committal name for such an object, so as to leave as an open question its identification with a protogalaxy, a compact elliptical galaxy, the nucleus of a diffuse galaxy, or a quasi-stellar object: the term 'galaxoid' will therefore be used—hopefully without prejudice.

Once again, both gravitational and magnetic energies will be released if the magnetic field and the gas can be de-coupled. This will not happen in magnetohydrodynamic theory, since the diffusion rate is extremely slow (in excess of 10<sup>20</sup> years even if the scale is only 1 pc.). Magnetohydrodynamic instabilities do not effect or permit de-coupling of the gas and magnetic field and so, presumably, will not provide an efficient acceleration mechanism. If the galaxoid contains a density gradient which is opposite in sign to that in a body supported by gas pressure, it will be unstable against the Rayleigh–Taylor<sup>14</sup> magnetohydrodynamic instability, unless the magnetic field exhibits a sufficient degree of shear. If there is sufficient shear (and some shear must always be present), the relevant instability will be the Coppi instability, which is resistive. This instability causes the plasma to break up into fine filaments and so permits rapid relative motion of the field and plasma, the growth time of the instability being the time of propagation of an Alfvén wave across the region of anomalous density gradient.

If gas pressure, radiation pressure and centrifugal force are all negligible in comparison with gravitational and magnetic forces, the magnetic energy and (negative) gravitational energy will be approximately equal. We assume that the galaxoid has a shape which may be adequately characterized by a single dimension  $R$ , an equivalent radius, and write:

$$W = G M^2 R^{-1} \approx 10^{8.8} M^2 R^{-1} \text{ erg} \quad (1)$$

and

$$W = \frac{1}{6} R^3 B^2 \approx 10^{1.2} R^3 B^2 \text{ erg} \quad (2)$$

where  $M$  is the total mass and  $B$  is the average intensity of the magnetic field.

Observations of the optical and radio emission associated with an explosion make it possible to set a lower limit to  $\Delta W$ , the change in  $W$  due to the explosion, and hence to  $W$ . In order to determine both parameters  $M$  and  $R$ , one further item of information is needed. For this reason, we shall now restrict our attention to the radio source 3C273 since the component 3C273B, which we identify with the galaxoid, exhibits a periodicity in its optical radiation of period 13 years (10<sup>8.6</sup> sec)<sup>3</sup>. Since the Alfvén speed has the mean value:

$$v_A = B(4\pi\rho)^{-1/2} \approx 10^{4.6} M^{1/2} R^{-1/2} \text{ cm sec}^{-1} \quad (3)$$

(the escape speed has approximately the same value), the oscillation period may be estimated to be:

$$\tau = R v_A^{-1} \approx 10^{3.4} M^{-1/2} R^{3/2} \text{ sec} \quad (4)$$

In order to estimate  $W$  for 3C273, it is necessary to estimate  $\Delta W$ . At the present rate of radiation, the jet 3C273A would have emitted 10<sup>57</sup> ergs or more since the flare. The energy of the magnetic field of the jet will not be counted since it is not assumed that the magnetic field is ejected with the particles. Moreover, the optical and radio emission of the  $B$  component is not regarded as a product of the flare. If the foregoing energy is only 10 per cent of the energy originally present in accelerated particles directly following the flare, and if this energy was only 1 per cent of the total energy released,  $\Delta W = 10^{60}$  ergs. If this were a substantial fraction of  $W$ , say 10 per cent, we would be led to the choice  $W = 10^{61}$  ergs. It is possible that  $\Delta W$  was a smaller fraction of  $W$ , but it is also possible that the energy in high-energy particles represents more than 1 per cent of the released energy. For example, it is possible that particles are accelerated in the shock front which must form ahead of the ejected gas; this process occurs in connexion with solar flares, giving rise to Type II radio bursts<sup>15</sup>. However, a factor of ten is not very important in the present exploratory calculation, so we adopt  $W = 10^{61}$  ergs.

The foregoing values for  $\tau$  and  $W$  lead to the following set of parameters for the galaxoid:  $M = 10^{43} \text{ g} = 10^{9.8} M_\odot$ ;  $R = 10^{17.8} \text{ cm} = 10^{1.3} \text{ pc.}$ ;  $B = 10^{4.3} \text{ gauss}$ ;  $v_A = 10^{9.2} \text{ cm sec}^{-1}$ . If the gas were predominantly hydrogen, the mean number density  $n$  would be 10<sup>13</sup> cm<sup>-3</sup>. The trapped magnetic flux  $\Phi = \pi R^2 B$  is found to be 10<sup>40.2</sup> gauss cm<sup>2</sup>. The question whether (general) relativistic effects are important cannot be answered without a detailed account of the way in which the mass and magnetic field distributions change with a change of linear scale. This question is complicated by the facts that the magnetic field which we associate with a galaxoid is open rather than closed, and that there is an exchange of dynamical and magnetic angular momentum during the process of contraction or expansion. Since the Schwarzschild radius for the foregoing mass is 10<sup>14.7</sup> cm, relativistic effects will show up only if there is a close approximation in the dependence of gravitational and magnetic energies on radius, and this seems to be unlikely. The Alfvén velocity and escape velocity are small enough to render relativistic effects unimportant in the plasma instability process, but large enough to permit the inferred turbulent velocities<sup>3</sup> of 10<sup>8.5</sup> cm sec<sup>-1</sup>.

In order to give a more detailed picture of a galaxoid, it is necessary to consider the process by which it is formed. If one takes the view that the magnetic field is created by the galaxoid, one must determine what remarkable mechanism can generate, rapidly enough, a magnetic field strong enough to balance gravitational attraction in a condensing body. If, on the other hand, one assumes that the gas condenses from a region permeated by a magnetic field, the magnetic field will be

compressed with the gas. If, at the very beginning of the condensation process, gravitational and magnetic forces are comparable in magnitude, then they will always be comparable, although which of the two is stronger may change during the evolution of the condensation. The latter hypothesis, which we now adopt, leads us to picture the galaxoid as a mass of gas trapping and compressing a large magnetic flux which, at large distances, connects with a weak intergalactic magnetic field. We may note that the stored magnetic energy has been derived from gravitational energy during the condensation process.

It is noteworthy that such a magnetic field configuration would form an 'hour-glass' configuration, comprising a pair of funnels which channel the inflowing gas directly into the galaxoid. If the gas from which the galaxoid condenses has significant angular momentum, this will lead to a distortion of the magnetic field into helical form; this will lead to shear in the magnetic field, and it also provides a mechanism for reducing the angular velocity of the central core, transferring the angular momentum of the core material to the surrounding shells and possibly to the intergalactic gas.

We now enquire whether this hypothesis could lead to a galaxoid with the parameters suggested for 3C273. We suppose this object to be formed from a region of space in which the number density of hydrogen atoms is  $n_0$ , the temperature is  $T_0$  and the magnetic field strength is  $B_0$ . We may determine approximately the radius of the boundary between the region in which gas is flowing into the galaxoid and the region in which gas is undisturbed by the galaxoid by equating the mean thermal energy of a hydrogen atom to its gravitational energy in the field of the galaxoid. Hence:

$$R_c = GMm/\chi T_0 \approx 10^{16.9} M T_0^{-1} \text{ cm} \quad (5)$$

At this boundary, the inflow velocity will be approximately  $(2GM/R_c)^{1/2}$ , so that the influx of mass is given by:

$$J = 4\pi R_c^2 n_0 m (2GM/R_c)^{1/2} \approx 10^{49.1} M^2 n_0 T_0^{-3/2} \text{ g sec}^{-1} \quad (6)$$

This represents an inflow of energy into the galaxoid of amount:

$$S = JGMR^{-1} \approx 10^{-56} M^3 R^{-1} n_0 T_0^{-3/2} \text{ erg sec}^{-1} \quad (7)$$

Following Sciamia<sup>14</sup>, we adopt  $n_0 = 10^{5.7} \text{ cm}^{-3}$ , but we choose  $T_0$  to be such as would lead to the formation of the galaxoid in a few times  $10^9$  years. The value  $T_0 = 10^4$  deg. gives  $R_c = 10^{23.9} \text{ cm} = 10^{5.4} \text{ pc.}$ ;  $J = 10^{26.8} \text{ g sec}^{-1} = 101.1 M_\odot/\text{year}$ ; and  $S = 10^{44.9} \text{ ergs sec}^{-1}$ . (If the mass of the inflowing gas is taken into account,  $R_c$ ,  $J$  and  $S$  are all increased.) Hence the rate of increase of mass of the galaxoid has the time scale  $10^{8.7}$  years. We now find that the flux trapped in the galaxoid can be explained by assuming that the strength of the intergalactic magnetic field is  $10^{8.1}$  gauss. This is considerably less than the value  $10^{7.7}$  gauss which Sciamia<sup>14</sup> estimates to be typical of small galactic clusters. It leads to a ratio of gas pressure to magnetic pressure of about 10:1.

It is interesting to see that the energy input is close in magnitude to the radio and optical output of the component 3C273B. This suggests that the radio and optical emission of this component is due to bremsstrahlung: the flat spectrum can be explained by a suitable distribution of density and temperature with radius, and the energy radiated can be made up by the energy flux of the inflowing gas.

The foregoing model of the magnetic field associated with 3C273 would lead one to expect that the strength of the field at the position of the emitting cloud 3C273A is about  $10^{-6}$  gauss. However, the value is likely to be higher, following the flare, for the following reason: In a body of the dimensions given, in which the magnetic field is as high as that quoted, synchrotron radiation of both electrons and protons is so high in intensity that charged particles will have no transverse energy when they leave the accelerating region. For this reason, one

would expect the jet to be directed along the local magnetic field; there will be no transverse pressure tending to expand the magnetic field in which the cloud is moving but, on the other hand, there will be a high longitudinal momentum tending to straighten the magnetic field lines and so to increase the strength of the field along the path of the cloud. If the accelerating process occurred in a region involving about 10 per cent of the flux of the galaxoid, one would infer from the diameter of the cloud ( $10^{22.3} \text{ cm}$ ) that the magnetic field strength is now about  $10^{-5}$  gauss. With this value, one is led to estimate that the total energy of relativistic electrons is about  $10^{58}$  ergs, in agreement with our earlier hypothesis. Since the acceleration mechanism is electromagnetic, and since the energies are relativistic, there is no reason to suppose that there is a great deal more energy in protons than in electrons. The maximum energy must be at least  $10^{12.4} \text{ eV}$ . The radiation lifetime of these electrons will be  $10^{4.6}$  years. It should, however, be emphasized that electrons will not radiate until they are scattered into transverse orbits by strong magnetic-field inhomogeneities. It seems that these inhomogeneities are most likely to arise at the shock front which must form near the interface of the expanding cloud and the inflowing gas.

Since the flare which gave rise to the jet associated with 3C273A released a substantial fraction of the stored energy of the galaxoid, the dimensions of the flare layer must have been comparable with the radius of the galaxoid. This indicates that the growth time of the instability must have been about  $10^{8.6} \text{ sec}$  (the same as the present period of oscillation). Since micro-flares are much more common than intense flares on the Sun, we should expect that the galaxoid would exhibit low-energy explosions more frequently than catastrophic explosions. This suggests that we should identify the 'flashes' which occur in 3C273B as 'microflares'. Since the time scale is  $10^{6.3} \text{ sec}$ , the dimensions of the associated flare layer must be about  $10^{15.5} \text{ cm}$ . The energy of the microflare, which is about  $10^{52.3} \text{ ergs}$ , must be derived from the change in gravitational energy of a mass of gas moving towards the central mass by a distance comparable with the thickness of the flare layer, together with the corresponding change in magnetic-field energy. Hence the mass must be about  $10^{36.3} \text{ g}$ ,  $10^{7.3}$  times the total mass. The 'horizontal' dimension may be larger, say  $10^{17} \text{ cm}$ , which is still considerably less than one light-month: the gas density in this region would then be  $10^{10.6} \text{ cm}^{-3}$ , a reasonable value for an outer layer of the galaxoid.

The picture which we have given of a galaxoid, and the way in which it is formed, suggests that it should be a common stage in the early development of a galaxy. The flare process provides a mechanism for the protogalaxy to disentangle itself from the magnetic flux in which it was formed, and so proceed with normal galactic evolution. The remnant (or remnants) of the original galaxoid would presumably constitute the galactic nucleus (or nuclei).

Since quasi-stellar galactic objects are rare, there must be something unusual about their origin. The galaxoid hypothesis provides a possible answer to this question: the maximum mass and energy attained by a galaxoid depend on its age at the time it suffers a 'fatal' galactic flare. A very symmetrical galaxoid should live to an old age, but an unsymmetrical galaxoid will die young. We may now interpret quasi-stellar objects as galaxoids which have condensed from an unusually orderly region of intergalactic space, such as a region of fairly uniform density, temperature, vorticity and magnetic field, possibly with the additional favourable circumstance that the directions of the vorticity and magnetic field vectors are almost parallel.

Confirmation of the following observations on quasi-stellar objects would favour the model here described: (1) These objects rarely if ever occur in galactic clusters. (2) The quiescent optical spectrum indicates a filamentary

structure associated with the ducting of inflowing gas clouds along magnetic flux tubes. (3) The quiescent radio emission (by the star-like component) exhibits some degree of circular polarization, indicating bremsstrahlung radiation from a plasma in a magnetic field. (4) Flares occur over a wide range of energy, the frequency decreasing as the energy increases. (5) The optical emission associated with a flare indicates a fine filamentary structure<sup>13,17,18</sup> (of scale 10<sup>8</sup> cm, more or less).

A more complete account of this theory will be published at a later date.

*Note added in proof.* The recent discovery of 'interlopers' (*New York Times*, Jan. 27, 1965), which appear to be quasi-stellar objects with little or no radio emission, fits neatly into the foregoing scheme; an 'interloper' may be simply interpreted as a galaxoid which has not yet suffered a significant galactic flare.

## HYDRATION KINETICS OF CALCIUM SULPHATE HEMIHYDRATE

By J. H. TAPLIN

C.S.I.R.O. Division of Applied Mineralogy, Chemical Research Laboratories, Melbourne, Victoria

THE most conspicuous feature of the hydration kinetics of calcium sulphate hemihydrate is the pronounced maximum in the rate which occurs near the mid-point of the reaction. It is generally agreed that the precipitation of gypsum controls the rate until the maximum, and thereafter the control passes to the dissolution of hemihydrate. Consequently the exact position of the maximum is of great interest because it indicates the relative importance of the two processes in determining the rate.

Previous workers have chosen to fit experimental data to integrated forms of their rate equations. This is a very insensitive test for the rate equations. For example, provided the rate maximum is sufficiently close to the mid-point, plots of rate versus  $F$  (the fraction reacted) may be of quite different shapes (Fig. 1a) and still give an approximately linear plot of  $F$  versus time on arithmetic probability paper (Fig. 1b).

Polak<sup>1</sup> and Schiller<sup>2</sup> have derived a kinetic model based on sets of uniform spheres. By absorbing the concentration difference and the numbers of particles into two empirical rate constants (this kind of rate constant has been discussed before<sup>3</sup>; empirical rate constant is a better description than experimental rate constant since the latter usually means the numerical value of a rate constant obtained by treating experimental data) the rate equation simplifies to:

$$1/R = 1/gF^{2/3} + 1/h(1-F)^{2/3} \quad (1)$$

where  $R$  is the rate  $= dF/dt$ ,  $F$  is the fraction reacted,  $g$  is an empirical rate constant for the precipitation of gypsum,  $h$  is an empirical rate constant for the dissolution of hemihydrate.

However, since the gypsum crystals are not a set of spheres of uniform size, the exponent of  $F$  is not 2/3 unless all the following conditions are met: (1) Each crystal of gypsum maintains a constant shape as it grows. (2) Nucleation of gypsum is confined to a short period near the beginning of the reaction. (3) Crystal growth is not appreciably affected by crystal-to-crystal contacts. (4) The number of growth defects on a given crystal face does not change with age or crystal size, that is, the linear growth rate of a given crystal face depends on the supersaturation only.

Similarly the hemihydrate particles are not of uniform size or spherical, and the exponent of  $(1-F)$  is unlikely to be 2/3 unless all the following conditions are met: (5) The hemihydrate particles are of uniform size.

Fig. 1. Three rate equations of the form:  $1/R = 1/gF^{2/3} + 1/h(1-F)^{2/3}$  with  $Y = 1.0$ ;  $X = 2/3, 1.0, 1.5$ ;  $g = 2.31, 4.00, 8.52$  and  $h = 5.13, 4.00, 3.37$ , respectively. a, Rate versus fraction reacted. The curves are easily distinguished; b, plots of fraction reacted versus time on arithmetic probability paper. The plots are approximately linear.

(6) The particles are not elongated or flattened. (7) All particles have the same reactivity.

Since all these conditions are not met, and since an exact model would require a quantitative description of the changing geometry of the system which is so far unattained, the following more general rate equation is advocated as a more realistic and accurate method of describing kinetic experiments in this system:

$$1/R = 1/gF^X + 1/h(1-F)^Y \quad (2)$$

where  $X$  and  $Y$  are parameters which depend on conditions (1) to (7) and which can be adjusted to give the best fit for any particular data. This equation will be applied to some data from an experimental investigation of the hydration kinetics of a gypsum plaster in order to illustrate the utility and the limitations of this approach.

The hydration kinetics of a commercial casting plaster (without retarder) were investigated by means of a conduction calorimeter. The copper base of the calorimeter formed part of the heat conduction path and was 4.75 cm in diameter. The calorimeter was calibrated with a dummy sample containing an electrical heater. The rate of hydration was determined from an equation:

$$dH/dt = k_1\Delta T + k_2(d\Delta T/dt) \quad (3)$$

where  $dH/dt$  is the rate of heat evolution,  $\Delta T$  is the difference in temperature between the calorimeter sample holder base and the water bath,  $k_1$  is a calibration constant determined from a steady-state calibration,  $k_2$  is a calibration constant determined from a cooling rate calibration.

The temperature rise in the calorimeter base was 2°–3° C and, since there was a temperature difference across the specimen, the average maximum rise in temperature in the specimen was about 4°–7° C. The data to be presented here have not been corrected for this temperature rise, although for this plaster I found a larger temperature co-efficient than reported by other workers<sup>4</sup>.

The following six experiments illustrate a variety of kinetic effects. *B 32*, a control; *B 44*, acceleration by addition of 1 per cent potassium sulphate; *B 48*, retardation by addition of 1 per cent calcium acetate; *B 46*, acceleration by addition of 20 per cent of gypsum; *B 27*, acceleration by grinding the hemihydrate with pestle and mortar; *B 74*, retardation by lack of stirring.

The ambient temperatures were between 20° and 23° C and the water to calcium sulphate ratio was unity. Specimens contained 2–9 g of plaster. The water and plaster were stirred with a glass rod in a small beaker for 60 sec before pouring into the calorimeter except that in experiment *B 74* the dry plaster was placed in the calorimeter and the water added from a pipette without mechanical stirring.

The temperature difference across the calorimeter was recorded automatically and the reaction rate found from equation (3). The fraction reacted was found by numerical integration. Equation (2) in the cross-multiplied form was fitted to the data by the method of averages. In order to fit the control experiments,  $X$  was taken as 0.8 and  $Y$  as 1.3. The empirical rate constants are shown in Table 1. Using these rate constants and the integrated

Table 1. THE EMPIRICAL RATE CONSTANTS OBTAINED BY FITTING A RATE EQUATION  $1/R = 1/gF^{0.8} + 1/h(1-F)^{1.3}$  TO EXPERIMENTAL DATA

Experiment	No.	Empirical rate constants ( $\times 10^3$ )	
		$g(\text{min}^{-1})$	$h(\text{min}^{-1})$
1 per cent potassium sulphate solution	<i>B 44</i>	48	132
Control	<i>B 32</i>	14	94
1 per cent calcium acetate solution	<i>B 48</i>	5.3	50
Addition of 20 per cent A.R. gypsum	<i>B 46</i>	68	68
Re-ground plaster	<i>B 27</i>	41	99
No stirring	<i>B 74</i>	11	54

Fig. 2. Calculated times for the reaction to reach successive values of  $F$ , the fraction reacted, plotted against the corresponding experimental times. The empirical rate constants from Table 1 and the integrated form of the rate equation were used to obtain the calculated times. The time intervals marked on the co-ordinates are: *B 44*, 1 min; *B 46* and *B 27*, 2 min; *B 32* and *B 74*, 4 min; *B 48*, 8 min

Fig. 3. Rate versus fraction reacted. The points are experimental data. The curves are drawn from the equation:  $1/R = 1/gF^{0.8} + 1/h(1-F)^{1.3}$ , where  $g$  and  $h$  are the appropriate empirical rate constants from Table 1

form of the rate equation, the time needed for the reaction to reach each experimental value of  $F$  was calculated and plotted against experimental time (Fig. 2). At least 91.5 per cent of the reaction is covered by the points in each plot. No data for  $F < 0.02$  or  $> 0.98$  were used.

The description of the experimental data by this equation leads to a simple interpretation of the experiments as follows:

(i) Neither grinding the hemihydrate nor adding gypsum greatly affected the rate of dissolution of hemihydrate, but the rate of precipitation of gypsum increased three and five times respectively.

(ii) Complete lack of stirring nearly halved the rate of dissolution but scarcely affected the rate of precipitation. (Increased stirring, on the other hand, increases the rate of precipitation but has no further effect on the rate of dissolution.)

(iii) A 1 per cent solution of potassium sulphate increased the rate of precipitation three and a half times and the rate of dissolution only one and a half times.

(iv) A 1 per cent solution of calcium acetate reduced the rate constants for precipitation and dissolution to one-third and one-half respectively.

Plots of rate versus fraction reacted (Fig. 3) show the extent to which the equations (continuous lines) fit the data (points). Since  $X$  and  $Y$  were chosen to fit the control experiments it is not surprising that the same equation does not fit too well for large additions of gypsum or for plaster which has been re-ground. If  $X$  and  $Y$  are varied from run to run a much better fit can be obtained but at the expense of the simple quantitative description since empirical

rate constants can be compared directly only when defined by the same function. The ascending arm of the rate curve is often approximately linear, but since the line extrapolates above the origin (especially for longer periods of stirring) it suggests that  $g$ , the empirical rate constant for precipitation, should be defined by the function  $(F + \alpha)^X$  where  $\alpha \approx 0.10$  and  $X \approx 1.5$ .

Comparing Figs. 2 and 3, it is seen that a plot of reaction rate versus fraction reacted is a more critical graphical test of a rate equation than is a plot of fraction reacted versus time.

There is little point in describing the kinetics of calcium sulphate hemihydrate by a rate equation with only one empirical rate constant or, if there are two, of assuming that they have a fixed ratio. The major interest in the system from the point of view of kinetics is in deciding the extent to which a given effect is due to a change in the rate of precipitation of gypsum, or in the rate of dissolution of hemihydrate (or perhaps in the rate of diffusion if this becomes rate controlling).

The equation:

$$1/R = 1/gFX + 1/h(1 - F)^Y$$

(where  $X$  and  $Y$  are adjusted for each batch of hemihydrate) is suggested as an improvement on the uniform spheres model (with  $X = Y = 2/3$ ) since the latter is unconvincing and fits experimental data only poorly.

## SODIUM-22 AND CAESIUM-134 IN FOODS, MAN AND AIR

By R. W. PERKINS and Dr. J. M. NIELSEN

Hanford Laboratories, General Electric Company, Richland, Washington

THE radionuclides sodium-22 and caesium-134 are present in the atmosphere in very low concentrations, but because of their relatively high biological uptake they are concentrated in food products and thus find their way to man. The radionuclide sodium-22 (2.6 yr.) is a naturally occurring isotope, being produced by cosmic ray spallation of argon in the atmosphere. Its presence in the atmosphere was first reported by Marquez<sup>1</sup>, who found 0.017 d.p.m./l. in rainwater at Rio de Janeiro. Its potential value as a tracer of atmospheric circulation has been recognized, and measurements for this purpose by Bhandari and Rama<sup>2</sup> have shown air concentrations ranging from 1 d.p.m./10<sup>6</sup> ft.<sup>3</sup> below the tropopause to 460 d.p.m./10<sup>6</sup> ft.<sup>3</sup> above the tropopause. Its production rate in the atmosphere is a function of the effective cosmic ray flux, and it increases by about an order of magnitude with latitude between the equator and the geomagnetic poles at elevations above the tropopause. However, its production rates at elevations below 10,000 ft. vary only slightly with latitude. An additional source of sodium-22 is from nuclear weapons testing, and it is possible that large amounts have been added to the atmosphere during the past atomic test series. The caesium-134 content of the atmosphere has resulted from atomic weapons testing and it appears that its main source is the  $n, \gamma$  reaction on inert caesium-133 with smaller amounts resulting from fission<sup>3</sup>.

The radionuclides sodium-22 and caesium-134 have been measured in air filter samples and other materials which were collected during the past few years as part of a comprehensive investigation of fall-out materials. Air filtration is performed with membrane filters<sup>4</sup> and the concentrations of 9-12 of the long-lived radionuclides are measured by direct counting in an anticoincidence shielded  $\gamma$ -coincidence spectrometer<sup>5</sup>. This instrument surveys the sample with two detectors and simultaneously meas-

ures and records the coincidence  $\gamma$ -ray energies in its 4096 channel multiparameter memory. The observed concentrations of sodium-22, caesium-134 and caesium-137 as measured at Richland, Washington, at a sampling point 15 ft. above the ground are recorded in Table 1. During 1962, relatively low volume sampling equipment was used to provide samples so small as to result in counting uncertainties of 10–20 per cent for sodium-22 and caesium-134 (and larger uncertainties during the period January–March, see Table 1); however, during 1963 the large composite samples ( $2 \times 10^6$  ft.<sup>3</sup>) permitted more precise measurements. It is of interest that the air concentrations of each of the radionuclides increased in 1963 by about a factor of 2 over the 1962 rates. The 1963 sodium-22 levels are about an order of magnitude greater than those reported for troposphere air<sup>2</sup> prior to the 1961 atomic tests. A small increase could result from the higher cosmic-ray production owing to the normal sunspot cycle, but the main contribution appears to be the past atomic weapons test series.

During late 1962 and January 1963, caesium radionuclide analyses were performed on the dust collected on the air filters of our laboratory. These are high-volume fibre-glass filters and are not designed for removal of very small particles. The observed caesium-134 to caesium-137 ratio on these filters was 0.016–0.017 (refs. 3 and 6). It is very significant that the relative amount of caesium-134 was 2–4 times higher than that found on membrane air filters collected during the same period of time. It is evident that the caesium-134 is in a greater isotopic abundance on large atmospheric dust particles which are preferentially held by the fibre-glass filters than on small particles which are all removed by the membrane filters<sup>4</sup>. This observation is in accordance with the methods of formation of the caesium isotopes. Caesium-137 is the daughter of xenon-137 (half-life, 3.8 min), while caesium-134 is formed directly either by the reaction caesium-133 ( $n, \gamma$ ) caesium-134, or as a direct fission product.

*Concentrations in foods and man.* Of particular interest in our work is the route by which sodium-22 finds its way to man. On the basis of chemical similarity one might suspect the same foods which carry the caesium radionuclides. The concentrations measured in several of these foods together with measurements from bioassays and estimated body burdens based on these bioassay measurements are recorded in Table 2. In addition to the samples obtained locally, Alaskan caribou, moose and

reindeer meat, and bioassay samples from Alaskan Eskimos were analysed and are included in Table 2. The whole-body concentrations of sodium-22 and the caesium radionuclides in Table 2 were estimated using biological half-lives<sup>7</sup> of 11 days and 140 days, respectively. It was assumed in this estimate that 90 per cent of the sodium and caesium excreted was in the urine and that the daily urinary excretion rate was 1.5 l. The major sources of sodium-22 in the foods considered are meat, milk, wheat and fresh-water fish, with smaller contributions coming from vegetables. The few food samples considered here are certainly not sufficient to give a complete picture of man's sodium-22 intake. However, they indicate the relative importance of different foods and suggest that the foods which carry caesium-137 to man are also the main sources of sodium-22. It is interesting to note that the elk tissue from Quinault, Washington, has sodium-22, caesium-134 and caesium-137 concentrations which are comparable with those in Alaskan caribou. Obviously, a small amount of this meat in the diet could provide the major source of these radionuclides.

The ratios of sodium-22 and caesium-134 to caesium-137 in the samples of Alaskan caribou meat taken just before and just after the 1961–62 test series show a considerable difference. The sodium-22 to caesium-137 ratio in samples taken after the tests (July 1963) was about ten times greater than in samples taken just before the tests, while the caesium-134 to caesium-137 ratio was lower by a factor of 4. This would suggest that during the past test series considerable amounts of sodium-22 were generated. It would also indicate that the major injection of caesium-134 into the atmosphere occurred in tests prior to the 1961–62 series.

We thank D. G. Watson, W. C. Hansen and H. E. Palmer for making the Alaskan and Quinault samples available for investigation. The work was carried out under contract AT(45-1)-1350 for the U.S. Atomic Energy Commission.

# POSTULATED CHEMICAL BASIS FOR OBSERVED DIFFERENCES IN THE ENZYMIC BEHAVIOUR OF CHYMOTRYPSIN AND TRYPSIN

By PROF. BERNARD F. ERLANGER, DR. WILLIAM COHEN\*, SPYROS M. VRATSANOS, HARRIET CASTLEMAN and A. G. COOPER

Department of Microbiology, Columbia University College of Physicians and Surgeons, New York 32, N.Y.

CHYMOTRYPSIN and trypsin are members of a group of hydrolytic enzymes with an activated serine residue which apparently participates in the catalytic mechanism<sup>1</sup>. The two enzymes share a number of other characteristics as well, some of which are as follows: Both are inactivated by organophosphorus compounds<sup>2</sup>; both can be inactivated by diphenylcarbamyl chloride, the rate of inactivation of  $\alpha$ -chymotrypsin being more rapid<sup>3</sup>; each contains the sequence Gly-Asp-Ser-Gly at its active centre<sup>1</sup>; both are amidases as well as esterases and, although their overall specificities differ, some overlap exists, for example, acetyl-L-tyrosine ethyl ester, a 'specific' substrate of chymotrypsin, is also hydrolysed by trypsin at about 1/13th the rate<sup>4</sup>; evidence for a similar catalytic pathway (including an acyl enzyme intermediate) has been obtained for both enzymes<sup>5</sup>; histidine residues have been implicated in their catalytic mechanism, and in both enzymes the two histidine residues are in close proximity<sup>6</sup>.

There is thus a remarkable similarity between the two enzymes, and Bender and Kaiser have suggested that "in all important mechanistic aspects, catalyses by trypsin and  $\alpha$ -chymotrypsin are similar"<sup>5</sup>. During investigations on the reactivation of the diethylphosphoryl (DEP) and diphenylcarbamyl (DPC) derivatives of  $\alpha$ -chymotrypsin and trypsin<sup>3,7</sup>, however, differences between the two enzymes became apparent. We wish to report on those and other differences and to show that they can be explained if it is postulated that the active centre of  $\alpha$ -chymotrypsin has a general acid not present at the active centre of trypsin.

In 1954, during investigations on the reactivation of DEP-chymotrypsin by hydroxylamine, it was reported by Cunningham<sup>8</sup> and later confirmed in this laboratory<sup>7</sup> that it was not possible to effect more than a 35-40 per cent return of activity regardless of the pH of the medium and the time allowed for completion of the process. We found, on the other hand, that complete reactivation could be obtained using formohydroxamic acid as the reactivator<sup>7</sup>. DEP-trypsin could be completely reactivated by either hydroxylamine or formohydroxamic acid<sup>7</sup> as could DPC-chymotrypsin and DPC-trypsin<sup>3</sup>. Thus, of all the derivatives examined, only DEP-chymotrypsin could not be completely reactivated by hydroxylamine. It was decided that this observation merited further investigation.

The object of the first series of experiments was to determine whether formohydroxamic acid would release the 60-65 per cent of the potential activity remaining after hydroxylamine treatment of DEP-chymotrypsin. DEP-chymotrypsin (0.4 mg/ml.), which was dissolved in 0.25 M *tris*-maleate buffer containing CaCl<sub>2</sub>, 0.01 M, pH 7.0, 1.5 M with respect to hydroxylamine, was incubated for 48 h at 25° C. Maximal reactivation was obtained after this period of incubation. One volume of the reactivated enzyme solution was then mixed with an equal volume of buffer containing hydroxylamine, 1.5 M, and formohydroxamic acid, 1.0 M. Parallel experiments were carried out with chymotrypsin. As shown in Table 1, addition of formohydroxamic acid after incubation with hydroxylamine was without effect.

\* Present address: Department of Biochemistry, Tulane University Medical School, New Orleans, La.

Table 1. REACTIVATION OF DEP-CHYMOTRYPSIN BY HYDROXYLAMINE FOLLOWED BY FORMOHYDROXAMIC ACID

	Activity* after treatment with 1.5 M NH <sub>2</sub> OH		Activity after additional treatment with 1.0 M formohydroxamic acid	
	0 h	48 h	Additional 24 h	Additional 48 h
DEP-chymotrypsin	0.2	27.5	21.4	24.4
Chymotrypsin	100.0	94.0	83.0	74.0

\* Assayed with N-acetyl DL-phenylalanine  $\beta$ -naphthyl ester<sup>7</sup>.

Apparently, therefore, treatment of DEP-chymotrypsin with hydroxylamine resulted in the formation of two products: active enzyme and a product incapable of reactivation by either hydroxylamine or formohydroxamic acid.

It occurred to us that the foregoing phenomenon might be related to the process of 'ageing', which had caused di-isopropylphosphoryl (DIP)-pseudocholinesterase, on standing for some time in solution, to be incapable of complete reactivation<sup>9</sup>. In this case it was found that some mono-isopropylphosphoryl (MIP)-pseudocholinesterase, a derivative refractory to nucleophilic attack, had been formed spontaneously from the DIP derivative. We therefore wished to determine whether our unreactivable chymotrypsin fraction was, analogously, mono-ethylphosphoryl (MEP)-chymotrypsin. Twenty-five mg of radioactive DEP chymotrypsin was incubated with 4 ml. of 2 M NH<sub>2</sub>OH in 0.05 M *tris*-chloride buffer, pH 7.0, for 48 h at 25° C. Following dialysis and lyophilization, the product was hydrolysed at pH 12.6, 100° C for 10 min, neutralized to pH 4 with concentrated hydrochloric acid, chromatographed on Whatman No. 1 paper in the solvent system *n*-butanol/acetic acid/water, 120:30:50, and then exposed to X-ray film for autoradiography. This procedure, as was shown by Berends *et al.*<sup>3</sup>, should have yielded diethyl phosphate and monoethyl phosphate from DEP-chymotrypsin and MEP-chymotrypsin, respectively. As shown in Fig. 1, treatment with 2 M NH<sub>2</sub>OH did indeed convert DEP-chymotrypsin to MEP-chymotrypsin in addition to yielding active chymotrypsin. *I*<sub>1</sub> and *I*<sub>2</sub> represent control experiments in which hydroxylamine was omitted from the solution. The major spots (*R*<sub>F</sub> 0.60)

Fig. 1. Autoradiograph of experiments designed to show whether hydroxylamine converted DEP<sup>32</sup> chymotrypsin to MEP<sup>32</sup> chymotrypsin

are diethyl phosphate.  $II_1$  and  $II_2$  represent experiments in which DEP-chymotrypsin was exposed to 2 M  $NH_2OH$ . Traces of diethyl phosphate are present, but the major spots with  $R_F$  0.37 are monoethyl phosphate. It should be noted that traces of monoethyl phosphate exist also in  $I_1$  and  $I_2$ , indicating that some spontaneous 'ageing' had occurred in the absence of hydroxylamine.

The following reaction, therefore, must have occurred:

Thus it was demonstrated that the partial conversion of DEP-chymotrypsin to MEP-chymotrypsin by  $NH_2OH$  is the side reaction responsible for the incomplete reactivation of DEP-chymotrypsin. It cannot occur to DPC-chymotrypsin or DPC-trypsin since there is only one susceptible ester bond—that involving the active serine residue. Hence, the diphenylcarbamyl derivatives are completely reactivated by hydroxylamine<sup>9</sup>.

As the side reaction does not occur during the reactivation of DEP-trypsin, we can postulate from the above that the functional groups at or near the active serine are not the same in  $\alpha$ -chymotrypsin and in trypsin. Although we cannot state with certainty that any difference is relevant to the catalytic mechanism of the enzyme, there is evidence that this is so. The evidence favours the hypothesis that  $\alpha$ -chymotrypsin has an additional electrophilic group which is favourably located to interact with the ethoxy groups of DEP as shown in scheme II. In this scheme, the fate of the hydroxylamine derivative is as described for another system by Jandorf<sup>10</sup>.

Fig. 2. Effect of pH on rate of reaction of diphenylcarbamyl chloride with trypsin (solid line).  $[E]_0 = 0.6 \times 10^{-4}$  M;  $[I]_0 = 1.2 \times 10^{-4}$  M; buffer, 0.08 M borate-maleate-acetate containing 0.056 M  $CaCl_2$  and 5 per cent acetone. Residual tryptic activity measured with  $\alpha$ -N-benzoyl-DL-arginine *p*-nitroanilide hydrochloride (BAPA)<sup>12</sup>. Dashed line taken from ref. 3.

Assuming the existence of this additional group (data will be presented below), the possibility that it might be part of the binding site of chymotrypsin was considered. If it were, it might be possible, by blocking this site with indole, to obtain complete reactivation with hydroxylamine. However, incubation of DEP-chymotrypsin with M  $NH_2OH$  in the presence of  $4 \times 10^{-3}$  M indole at pH 7 (0.057 M *tris* buffer) for 48 h did not increase the yield of active enzyme.

There is further evidence of the existence of the additional group in chymotrypsin. An unexpected difference between chymotrypsin and trypsin was revealed during an investigation of their reaction with diphenylcarbamyl chloride. We reported elsewhere<sup>3</sup> that a plot of pH against rate of inactivation of chymotrypsin gave a bell-shaped curve with a maximum at pH 7.8. Similar experiments with diphenylcarbamyl chloride and trypsin gave the curve shown in Fig. 2. For comparison, the curve for the reaction with  $\alpha$ -chymotrypsin is also shown. As can be seen, the curve for the reaction with trypsin starts to descend at pH 9-9.5 instead of having a maximum at 7.8. If the chymotrypsin curve can be considered to be a reflexion of a reaction involving two groups, one with a  $pK_a$  of 6.6 and the other with a  $pK_a$  of 8.7<sup>3</sup>, we can conclude that trypsin lacks the latter group. This would be in accord with the previous results and with the hypothesis that chymotrypsin has an additional group at its active site. On the other hand, the curve in Fig. 2 is compatible with the participation of a group with a  $pK_a$  near 10.

It has recently been shown by Trowbridge and collaborators<sup>11</sup> that the tryptic hydrolysis of the specific substrate  $\alpha$ -N-*p*-toluenesulphonyl-L-arginine methyl ester hydrochloride (TAME) is activated by the substrate. In investigations in this laboratory, we found no substrate activation of the chymotryptic hydrolysis of the specific substrate glutaryl-L-phenylalanine *p*-nitroanilide (GPANA) (Erlanger and Cooper, in preparation). Since substrates of trypsin contain ammonium or guanidinium groups, we also investigated the effect of ethylamine on the chymotrypsin hydrolysis of GPANA; neither inhibition nor activation was observed. Thus, again, we find a difference between the manner in which the two enzymes attack their respective specific substrates.

A clue as to the reason for this difference lies in the finding of Inagami and Murachi<sup>12</sup>, and the additional investigations of Erlanger and Castleman<sup>13</sup>, that the tryptic hydrolysis of acetyl glycine ethyl ester (AGEE) is enhanced by a large number of amines, among them ethylamine and cyclopropylamine. We now find that the hydrolysis of AGEE by chymotrypsin is not affected in any way by 0.05 M ethylamine or cyclopropylamine under conditions similar to those used with trypsin<sup>13</sup>. Our recent examinations show, furthermore, that the rate-determining step in the tryptic hydrolysis of AGEE is the formation of the acyl enzyme intermediate. Thus the amines increase the rate of this step of the reaction.

All the foregoing findings can be reconciled if we postulate that trypsin uses an ammonium or guanidinium group of the substrate or activator as the general acid that it lacks at its active centre. In other words, its hydrolysis of a specific substrate occurs via the same mechanism as does the chymotryptic hydrolysis of specific substrates except that trypsin makes use of part of the substrate in its catalytic mechanism.

It might follow from these suggestions that reactivation of DEP-trypsin by hydroxylamine would be incomplete in the presence of ethylamine or cyclopropylamine, since, by analogy with the results obtained with DEP-chymotrypsin, some MEP-trypsin would be formed. This possibility was investigated using 0.1 M ethylamine and 0.1 M cyclopropylamine. No decrease in the extent of reactivation could be detected with either amine. However, in <sup>32</sup>P experiments analogous to those run with radioactive DEP chymotrypsin (the results of which were presented in Fig. 1), small amounts of a substance with the *R<sub>F</sub>* of monoethyl phosphate were found when either of the two amines were present with 2 M NH<sub>2</sub>OH but not when they were absent. Perhaps suitable conditions can be found to increase the yield of MEP-trypsin.

To summarize, the following differences between chymotrypsin and trypsin have been found: (a) Hydroxylamine can completely reactivate DEP-trypsin but not DEP-chymotrypsin. Reaction with the latter leads to the formation of some MEP-chymotrypsin which cannot be converted to active enzyme; (b) MEP-trypsin apparently can result from the reaction of DEP-trypsin with hydroxylamine only if ethylamine or cyclopropylamine is present; (c) ethylamine and cyclopropylamine can accelerate the tryptic hydrolysis of AGEE but have no effect on its chymotryptic hydrolysis; (d) the tryptic hydrolysis of specific substrates is subject to substrate activation. The hydrolysis of specific substrates by chymotrypsin is not activated by substrates, nor is it affected by ethyl or cyclopropylamine; (e) the curve relating pH to the rate of reaction of  $\alpha$ -chymotrypsin with diphenylcarbamyl chloride has a maximum at pH 7.8. That of trypsin with diphenylcarbamyl chloride is essentially 'S'-shaped up to pH 9.0-9.5.

The foregoing findings agree with the hypothesis that chymotrypsin has an additional general acid at its active centre. This group, although not absolutely necessary for the catalytic mechanism, may increase the efficiency of the enzyme. Trypsin lacks this group but can utilize the ammonium or guanidinium group of its specific substrate for the same purpose. If absent from the substrate, these groups, in certain circumstances, can be added as aliphatic amines or alkyl guanidines. The postulated catalytic mechanism of chymotrypsin may be schematically represented as is shown in III.

BH<sup>+</sup> represents the general acid present at its active centre but not at that of trypsin. Trypsin, on the other hand, can use the amine or guanidinium groups of specific substrates or of a large number of aliphatic compounds for the same purpose. The designation of two histidines as participants in the catalytic mechanism is an extension of the findings and suggestions of Neurath and his collaborators<sup>6</sup> and of Hartley<sup>14</sup>. In this scheme they function alternately as general acids and general bases.

The scheme postulates that BH<sup>+</sup> by polarizing the C=O bond increases the net positive charge on the carbon and facilitates a nucleophilic attack on the substrate by the oxygen atom of serine. It is not absolute necessary to the catalytic mechanism but serves to increase the rate of the acylation step. Kupcham *et al.*<sup>15</sup> have shown that this type of polarization can increase the rate of solvolysis of strophanthidin-3-acetate to four times that of coprostane-3 $\beta$ -5 $\beta$ -diol 3-monoacetate in which the additional C=O polarization cannot take place. Thus, finding that the hydrolysis of AGEE (which lacks an NH<sub>3</sub><sup>+</sup> group) by chymotrypsin is about 3  $\times$  faster than its tryptic hydrolysis<sup>12</sup> accords with our hypothesis. The nine-fold increase in the rate of the tryptic hydrolysis of AGEE when ethylamine is present<sup>3,12</sup> is also in reasonable agreement with the postulated role of RNH<sub>3</sub><sup>+</sup> as the BH<sup>+</sup> group in the suggested mechanism. Apparently the BH<sup>+</sup> group does not participate in the deacylation step since the pH-rate profile of this step is sigmoidal for both trypsin and chymotrypsin<sup>16,17</sup>. It is possible that a conformational change accompanying acylation of the enzyme displaces this group. In the reaction scheme, water is shown as the attacking group; the nucleophile may also be NH<sub>2</sub>OH or the unionized species of a hydroxamic acid (cf. ref. 7).

As another consequence of the suggested function of the BH<sup>+</sup> group, the pH-rate profile for the acylation step of chymotryptic catalysis should not be truly bell-shaped. Rather than approaching zero on the basic side of the curve, it should tend towards a value consistent with the rate of the reaction in the absence of the polarizing BH<sup>+</sup> group. A search of the literature reveals that, in those cases examined (for example, see ref. 18), although bell-shaped curves are drawn, the actual data, in fact, indicate a levelling-off of the rate at a pH in the neighbourhood of 9.5-10.0. With respect to the acylation of trypsin, the shape of the curve would depend on the pK<sub>a</sub> of the amine or guanidine derivative when bound to the enzyme. In most cases it should be broader than the chymotrypsin curve.

The identity of the additional electrophile in chymotrypsin cannot be ascertained from these investigations. Presumably it may be an amino group. Although man-

investigations (see, for example, ref. 19) have shown that amino groups are not necessary to the catalytic mechanism of chymotrypsin, they do not rule out an auxiliary function, as postulated. In fact, it has been reported<sup>19</sup> that, while extensive acetylation of chymotrypsin caused a loss of specific activity, the specific activity of acetylated trypsin was the same as that of native trypsin. This could have been predicted from the hypothesis advanced here. Earlier experiments in this laboratory<sup>20</sup> yielded evidence for an additional conformation-sensitive group (other than serine) at or near the active centre of chymotrypsin. The imidazole function of histidine and the hydroxyl group of tyrosine were eliminated as possibilities. On the other hand, the data were consistent with the involvement of an amino group, perhaps the same group postulated as participating as the general acid in the scheme described in this article.

The very interesting findings of Hess and his collaborators<sup>21</sup> implicate the  $\alpha$ -amino group of the N-terminal isoleucine in the catalytic mechanism. This group, however, exists in trypsin also<sup>22</sup> and thus is probably not that postulated in our reaction scheme.

Of course, it is not the purpose of this article to suggest that there exists only one difference between the active centres of trypsin and chymotrypsin. Structural investigations<sup>6,14</sup> have shown otherwise. Moreover, the rates at which trypsin splits substrates containing arginine and lysine are several orders of magnitude higher<sup>4</sup> than the rate at which it hydrolyses AGEE, even in the presence of amines<sup>3</sup>. Differences therefore must exist in those portions of the active centre responsible for orientation and 'freezing' of the substrate into its 'correct configuration'<sup>23</sup>, that is, in the portions responsible for specificity. A discussion of this aspect of the problem is beyond the scope of this article.

One of the questions that remain concerns the ability of formohydroxamic acid to reactivate DEP-chymotrypsin completely. Why does it not, like hydroxylamine, cause the concomitant formation of MEP-chymotrypsin? This, however, is only one of a number of instances in which hydroxylamine behaves anomalously. For example, its pH-rate profile for the reactivation of DEP-trypsin and

DEP-chymotrypsin is bell-shaped<sup>7</sup>; by analogy with its reaction with other acyl enzymes (including DPC-trypsin and DPC-chymotrypsin) it should be sigmoidal. On the other hand, the pH-rate profile for the reactivation of DEP-trypsin and DEP-chymotrypsin by hydroxamic acids is sigmoidal if one assumes that the nucleophilic attack is made by the acid rather than the ionized species<sup>7</sup>. It is hoped that further investigations will clear up these discrepancies.

## CHEMICAL CARCINOGEN AND ONCOGENIC VIRUS: A POSSIBLE INTERACTION MECHANISM

By P. E. HUGHES\*

Department of Pathology, University of Melbourne, Victoria, Australia

**M**ANY diverse agents, chemical, physical or viral in nature, are now known to cause tumours in particular conditions. Several authors have reported synergism between chemical carcinogens and viruses<sup>1</sup>, but so far no common step in the various processes by which these factors act has emerged.

Many chemical carcinogens bind to cytoplasmic protein; thus, following the demonstration of the binding of hepatocarcinogenic aminoazo dyes to cytoplasmic liver proteins<sup>2</sup>, similar findings have been made with acetylaminofluorene in rat liver<sup>3</sup> and aromatic polycyclic hydrocarbons to mouse skin<sup>4,5</sup>. In each of these, there was a quantitative relationship between carcinogenicity and binding to a soluble cytoplasmic protein with characteristic electrophoretic properties. In almost all cases this protein is deleted from the tumours afterwards induced<sup>6-7</sup>.

These and other investigations have yielded an impressive amount of correlative data which point strongly to a causal association between protein binding and carcino-

genesis. In contrast to the large volume of work associating protein-binding with carcinogenesis, there have been few reports of the interaction of carcinogens with DNA<sup>8,9</sup>. However, it must be realized that present technical limitations could preclude the demonstration of carcinogen-DNA complexes involving hydrogen bonding or transient anion-cation complexes which could be of critical importance in carcinogenesis.

If protein-binding is of causal significance in carcinogenesis, and since all malignant change is heritable, carcinogens must bind to a protein having some genetic function. Interaction of a carcinogen with soluble cytoplasmic protein could produce a heritable change in a cell by way of: (a) induction of a 'somatic mutation'; (b) inactivation of a repressor protein; or (c) activation of a latent oncogenic viral infection.

(a) 'Somatic mutation' hypothesis. Protein-binding of carcinogens may effect changes in cellular DNA function if the protein concerned is a gene stabilizer, a gene suppressor or part of the protein moiety of the mitotic spindle

\* W. J. Kilpatrick Fellow, Anti-Cancer Council of Victoria.

Fig. 1. Diagram illustrating postulated site of action of carcinogen on cellular repressor and means of perpetuating the effect

apparatus. I myself<sup>10</sup>, from a study of the localization of protein-bound tritiated carcinogen in regenerating rat liver, could find no evidence in support of any of these hypotheses.

(b) *Binding to repressor proteins.* It has been suggested<sup>11</sup> that carcinogens may act by binding to repressor proteins. In Fig. 1 the regulator gene (RG1) produces a repressor protein (REP1) which represses the operator gene (OPG) governing the operon (OP). If the carcinogen inactivated the repressor protein (REP1), then the operon (OP) could produce product E. If product E stimulated another regulator gene (RG2) to produce another repressor (REP2) which, in turn, repressed RG1, then the carcinogen would only have to be present for sufficient time to enable enough of product E to accumulate to stop production of REP1 for the process to become self-perpetuating.

Such a scheme would require the appearance of two new cytoplasmic proteins, E and REP2, in pre-neoplastic tissues. The finding<sup>12</sup> that carcinogenic azo-dyes and 2-acetylaminofluorene, but not the non-carcinogenic 2-methyl-4-dimethylaminoazobenzene, increase slow-*h*<sub>2</sub> proteins may be relevant.

(c) *Activation of a latent viral infection.* Many viruses, like herpes simplex, cytomegalovirus and adenovirus, often produce latent infection in mammalian cells. The number of viruses known to have oncogenic potential is steadily increasing. Some of these, like SV40 and adenovirus, were not previously suspected to be oncogenic. Even viruses with no known oncogenic potential, such as vaccinia, can increase the incidence of chemically-induced tumours<sup>1</sup>.

If the role of a chemical is to activate a pre-existing latent oncogenic viral infection so as to make it overt, then the carcinogen would only need to act for an interval sufficient to enable the inactivation of a repressor of viral oncogenesis. Thus the point of biochemical attack on the cell by the carcinogen need not be at a genetically determinant level.

If, in Fig. 1, we associate virus (PV) with the operon, then the inactivation of repressor REP1 by carcinogen could enable PV to produce E and so initiate a malignant change. In such a scheme X-rays would be carcinogenic through the production of a mutation in one of the relevant genes, chemical carcinogens by inactivating repressor REP1, and oncogenic viruses through association with operon OP to produce, in some particular circumstances, sufficient of E to initiate a malignant change.

The importance of immune responses in protecting against polyoma oncogenesis has often been stated. However, the effects of thymectomy on polyoma carcinogenesis<sup>13,14</sup> and on the induction of tumours by 3:4-benzpyrene<sup>15</sup> need not necessarily have an immunological basis. An alternative explanation could involve a cytoplasmic repressor protein which needs a thymic hormone as a prosthetic group for repressor function. Carcinogens could compete with such a hormone at specific reactive sites and give rise to inactive repressor.

It is possible that, for a virus such as polyoma to be oncogenic in suckling mice, it must gain access to the cell before the production of REP1. REP1 may not be produced in mice in the first few days of life. Penetration

of polyoma virus into the cell, after production of REP1 has begun, would then lead to its incorporation into the host genome but with no overt oncogenic activity produced. Operon OP may have evolutionary significance being functionally active in rapid growth and differentiation during embryonic life. At or shortly after birth production of REP1 would control this process. extraneous genetic material is incorporated into the operon, subsequent activation could yield aberrant growth characteristic of neoplasia.

On this hypothesis, if polyoma virus and REP1 could be introduced simultaneously into the cells of susceptible suckling mice, the introduced REP1 could possibly preclude malignant transformation by the virus occurring in the infected cells.

Certain technical difficulties are involved in such an experiment. First, most biochemical work on carcinogen binding has been performed using rat liver, but no virus oncogenic for this organ, is available.

Since fractionation procedures for rat liver cytoplasmic proteins have been developed and this material is available in quantity, it was used, since, if REP1 is neither organ nor species-specific, it could be effective in mice.

Secondly, it is not certain that this particular protein would enter cells, but, as the dye-binding protein is one of the most basic in rat liver and the virus is negatively charged, the protein may adsorb non-specifically to virus. Virus enters cells by pinocytosis<sup>16</sup> and under these conditions protein could also enter either incidentally or adsorbed to virus.

Thirdly, it is possible that some protein may act not specifically in inhibiting the replication of viruses, and it is necessary to incorporate adequate control groups in the experiment. Thus the tumour incidence following the injection of polyoma virus plus protein prepared from normal rat liver (active REP1) either with or without *in vitro* exposure to carcinogen can be compared with the following virus plus buffer (no REP1), virus plus protein prepared from carcinogen-fed rat liver (REP1 rendered functionally inactive by covalently bound carcinogen) and virus plus protein prepared from aminoazo dye induce hepatomata (REP1 missing from tumour).

The results of these investigations are reported here.

All water used was double glass distilled.

'Carbowax MW 6,000' (Union Carbide Co., St. Kild Road, Melbourne) was dialysed against two changes of water and dried. 3'-Methyl-4-dimethylaminoazobenzene (3'MeDAB), m.p. 119°-120° C, was prepared by the method of Giese, Miller and Baumann<sup>17</sup>. Protein solution were stored at 2° C. All possible operations were carried out in a cold room 2°-4° C and completed in 5-6 days after isolation of the original material.

*Preparation of livers.* Male Sprague-Dawley rat (180-240 g) were fed a semi-synthetic diet<sup>18</sup> either unmodified (control group) or containing 0.06 per cent 3'MeDAB for 10 days. The rats were then injected intra peritoneally with 1 ml./100 g body-wt. of sunflower oil (control group) or 1 ml./100 g body-wt. of a 2 per cent solution of 3'MeDAB in sunflower oil (dye-fed group). Two days later their livers were perfused *in situ* via the portal vein with sodium chloride solution (0.15 M, 25 ml. at 37° C. The livers were removed, washed with 0.25 M sucrose at 0° C, minced with scissors and homogenized in pairs, in sucrose (0.25 M, 30 ml.) at 0° C for 2 min in a glass homogenizer. Some of the livers from rats on control diets were homogenized in sucrose solution alone while to others a solution of 3'MeDAB in sunflower oil (2 per cent, 0.5 ml.) was added before homogenization.

Aminoazo-dye-induced hepatomata were dissected free from surrounding liver tissue and homogenized in 0.25 M sucrose as above.

The homogenates were centrifuged at 28,000g for 1 h and the sediments discarded. Thus four liver protein solutions were obtained: (a) from rats on control diet; (b) from rats on control diet plus *in vitro* exposure of live;

proteins to 3'MeDAB; (c) from rats on diet containing 3'MeDAB; (d) from aminoazo-dye-induced hepatomata.

In initial experiments homogenates from rats of groups (a) and (c) were prepared; in later experiments all four groups were included each time.

**Chromatography on ion-exchange cellulose.** DEAE cellulose (Eastman Kodak Co., Rochester, New York) was suspended in pH 7.9 phosphate buffer (0.1 M) and repeatedly filtered and resuspended in starting buffer (0.005 M phosphate, 0.005 M chloride, pH 7.9). The suspension was evacuated with a water pump, poured into the column and packed with a head of buffer so that 12 g of DEAE cellulose gave a length of 20 cm column material. The final supernatant fractions prepared from two livers of rats of groups (a), (b), (c) and (d) were dialysed in a single vessel containing 6 l. of buffer solution (0.005 M phosphate, 0.005 M chloride, pH 7.9) at 2° C. Each dialysate was concentrated to 15–20 ml. by dialysis against a slurry of 'Carbowax' in the same buffer.

The protein solutions were equilibrated overnight by dialysis against 6 l. of this buffer and chromatographed on DEAE cellulose columns, using similar buffer for elution, at a rate of 30 ml./h. Fractions of 5 ml. were collected and the optical density at 280 m $\mu$  was recorded. In accordance with the findings of Whitcutt, Sutton and Nunn<sup>19</sup>, the dye-binding protein was found in the first peak of eluted material (usually fractions 8–18).

**Estimation of azo dyes associated with protein.** For dye estimations the method of Dijkstra and Joubert<sup>20</sup> was used for free dye and that of Miller and Miller<sup>2</sup> for protein-bound dye.

Dye estimations on 100-mg samples of individual protein preparations (first peak from DEAE cellulose) from dye-fed rat liver showed optical densities  $E_{520}$  between 0.740 and 0.990 for protein-bound dye and  $E_{565}$  between 0.067 and 0.180 for free dye.

Levels of free dye per 100 mg protein prepared from livers of rats on control diet but homogenized in the presence of free dye had  $E_{565}$  values from 0.098 to 0.210.

**Preparation of protein inocula.** The 'first peak' proteins from all DEAE cellulose columns were collected and concentrated by dialysis against a slurry of 'Carbowax' in buffer (0.03 M phosphate, 0.11 M chloride, pH 7.0). If any protein solution showed an undue precipitate during dialysis all the protein preparations of that group of two or four were discarded and fresh preparations made.

The concentration of protein in the solutions for inoculation into mice was adjusted so that the solutions had an optical density at 280 m $\mu$  of 27.1–29.8. Attempts to sterilize these solutions using 'Millipore' filters were unsuccessful.

Two thousand units of penicillin and 1,000  $\mu$ g of streptomycin per ml. were added to all protein inocula.

Most protein inocula were used within 5 (never more than 6) days following the killing of the rats and were not frozen at any time. Preliminary experiments show that injection of 0.1 ml. of these protein solutions into newborn mice produced no sign of toxicity.

**Virus.** Polyoma virus obtained from Dr. W. P. Rowe was grown in primary cultures of mouse embryo fibroblasts<sup>21</sup> and gathered at maximum cytopathic effect. The cultures were pooled, the virus was freed from cells by ultrasonic vibration and the preparations were snap frozen and stored at –70° C. The stock had a haemagglutination titre of 2,400 per ml. when tested against 0.4 per cent guinea-pig red cells by the technique of Rowe *et al.*<sup>21</sup>.

**Mice.** Swiss albino mice from a colony maintained in a separate building from the experimental animals were used. Random samples of 12 mice from the breeding colony were screened for polyoma antibody by the technique of Rowe, Hartley, Law and Huebner<sup>22</sup>. All sera were negative.

The mice were bred as required and used when less than 36 h old. Litter mates were distributed at random among

foster mothers and were injected with either 0.1 ml. of buffer (0.03 M phosphate, 0.11 M chloride, pH 7) containing 200 units of penicillin and 100  $\mu$ g streptomycin or with 0.1 ml. of protein preparation intraperitoneally.

Equal volumes of buffer or protein solutions were mixed with viral preparations and allowed to stand for 2 h at 0° C. Two hours after the initial buffer or protein injection the mice were inoculated with 0.1 ml. of the corresponding viral mixture. This was given in the nape of the neck by a fine-gauge needle introduced through the buttock. As soon as the injection bleb in the neck had subsided the mice were replaced with their foster mothers. For each batch of proteins randomized litter mates of all groups were injected with the same dose of virus.

Preliminary experiments showed that injection of undiluted virus produced much runting, while dilutions of 10<sup>-3</sup> (using medium 199 for dilution) gave too low an incidence of tumours to be of use. Dilutions in the range 10<sup>-0.75</sup>–10<sup>-1.5</sup> gave 25–30 per cent tumour incidence in the mice used and were used in subsequent experiments.

The mice were weaned on the 21st day and afterwards fed on 'Barastoc' and greens. No attempt was made to segregate the sexes and any litters were removed daily. The animals were examined weekly for tumours and all were killed and necropsied at 22 weeks.

Fifteen new-born mice were injected intraperitoneally with 0.1 ml. of protein solution obtained from livers of rats on control diet with *in vitro* exposure to 3'MeDAB and 0.05 ml. of the same solution subcutaneously and kept for 22 weeks in an animal house free from polyoma.

Animals were scored depending on whether or not tumours had developed within 22 weeks, no extra weight being given to those animals having multiple tumours. Mice given protein with dye adsorbed *in vitro* only showed no tumours. In all the groups of mice given polyoma virus, typical neck and breast tumours were commonly found. No significant differences in sites of tumour development were found between any of the groups and no liver tumours were found in any mouse.

The cumulative tumour incidence in various groups is shown in Table 1. Some mice died from maternal neglect, trauma or shock after injection. Among the animals surviving longer than one week after injection were several runt mice. Many of these died long before the termination of the experiment without developing tumours. In particular, those mice treated with protein from aminoazo dye-fed rat liver protein and viral dilutions of 10<sup>-0.75</sup> and 10<sup>0</sup> showed a very high incidence of runting. The percentage cumulative tumour incidence in these groups of mice, in particular those given 10<sup>0</sup> virus dilution, was lower than that in mice given corresponding protein and 10<sup>-1.5</sup> dilution of virus inoculum. It is possible that the runt mice dying early in the experiment would have been more likely to develop tumours if they had survived; this is suggested by the dose-response curves of Kraemer<sup>23</sup>.

It can be seen that there is a trend in those mice given normal liver protein to develop fewer tumours with polyoma virus than those given other proteins.

$\chi^2$  tests were applied to each of the small groups at each virus dilution, but with the numbers of animals used

Table 1. INCIDENCE OF TUMOURS IN MICE GIVEN POLYOMA VIRUS AND VARIOUS PROTEIN FRACTIONS

Treatment groups	No. of surviving mice*	No. of mice developing tumours	Percentage tumour incidence
Virus dilution Protein inoculum			
10 <sup>-1.5</sup> Buffer	50	14	28
Dye-fed rats	41	11	27
Normal rats	46	4	9
10 <sup>-0.75</sup> Buffer	56	16	29
Dye-fed rats	38	10	26†
Hepatoma	30	8	27
Normal rats + <i>in vitro</i> dye	53	6	11
Normal rats	54	7	13
10 <sup>0</sup> Buffer	54	20	37
Dye-fed rats	24	5	21†
Normal rats	37	6	17

\* Animals dying without tumours during experiment are omitted.

† These groups showed high incidence of runting.

differences significant at a 5 per cent level were only found occasionally—between buffer and normal liver protein groups, virus  $10^0$  and between buffer and *in vitro* dye protein virus  $10^{-0.75}$ .

However, when the groups at the  $10^{-0.75}$  dosage level are pooled the numbers are large enough to show significant differences. Thus the pooled groups given buffer only, hepatoma protein and aminoazo dye-fed rat liver protein are significantly different (at a 1 per cent level) from the combined groups given proteins from normal rats. The control group is not significantly different from the pooled groups given hepatoma and dye-fed liver proteins, but differs at a 5 per cent level from the combined groups given protein from normal rats. Likewise, the pooled groups of hepatoma and dye-fed liver proteins differ from the two groups given normal liver protein (< 5 per cent level). The results of the  $\chi^2$  tests are shown in Table 2.

Table 2. RESULTS OF  $\chi^2$  TESTS COMPARING NUMBER OF MICE WITH TUMOURS VERSUS (/) NUMBER WITHOUT TUMOURS

Virus	Groups compared Protein	$\chi^2$	Significance (one degree of freedom)
$10^{-0.75}$	Buffer/hepatoma	0	—
	Buffer/dye <sup>1</sup>	0	—
	Buffer/dye <sup>2</sup>	4.02	5% level
	Buffer/normal liver	3.16	—
	Hepatoma/dye <sup>1</sup>	0.06	—
	Hepatoma/dye <sup>2</sup>	2.22	—
	Hepatoma/normal liver	1.62	—
	Dye <sup>1</sup> /dye <sup>2</sup>	2.48	—
	Dye <sup>1</sup> /normal liver	1.83	—
	Dye <sup>2</sup> /normal liver	0	—
$10^{-1.5}$	Buffer/dye <sup>1</sup>	0.01	—
	Buffer/normal liver	4.66	5% level
	Dye <sup>1</sup> /normal liver	3.81	—
$10^0$	Buffer/dye <sup>1</sup>	1.83	—
	Buffer/normal liver	3.70	—
	Dye <sup>1</sup> /normal liver	0.01	—
$10^{-0.75}$	Buffer + hepatoma + dye <sup>1</sup> /dye <sup>2</sup> + normal liver	7.35	1% level
	Buffer/hepatoma + dye <sup>1</sup>	0	—
	Buffer/dye <sup>2</sup> + normal liver	5.70	5% level
	Hepatoma + dye <sup>1</sup> /dye <sup>2</sup> + normal liver	4.91	5% level

Exposures to dye: dye<sup>1</sup> = *in vivo*; dye<sup>2</sup> = *in vitro*.

The experiment was based on the hypothesis that the carcinogen-binding protein(s) is a repressor of viral oncogenesis. The results are reported for general interest and in the hope that other laboratories may repeat the experiment.

In the system used the observed differences in tumour incidence between groups are small. The individual groups at any dosage level of virus are, in general, too small to show significant differences. However, if the groups are pooled in various ways the results become significant at a

5 per cent level in combinations which support the original hypothesis. It must be remembered that the protein inoculum in every case is heterogeneous (each may be resolved into 5 or 6 peaks on carboxymethyl cellulose columns) so that the inoculum consists of mixed proteins plus hypothetical active repressor in the proteins from normal rat livers, mixed basic proteins plus hypothetical inactive repressor in the preparations from dye-fed rat liver and mixed basic proteins without repressor in the hepatoma proteins. The differences between the first of these groups and the others thus suggest that the lower tumour incidence is not simply a matter of non-specific antiviral activity on the part of proteins in the mixture. Thus the results support the hypothesis although, no doubt, other explanations may be advanced.

Further investigations are proposed to test the protective action of this protein on the development of polyoma 'microtumours' in hamster cell lines in tissue culture.

I thank Dr. D. O. White for the virus preparations and Miss A. Doig for her statistical advice.

## BIOSYNTHESIS OF NIACIN RIBONUCLEOTIDE FROM QUINOLINIC ACID BY MYCOBACTERIA

By DR. KIYOSHI KONNO, KOTARO OIZUMI and SUTEMI OKA

Research Institute for Tuberculosis and Leprosy, Tohoku University, Sendai, Japan

MYCOBACTERIA are able to grow in vitamin-free synthetic media and produce niacin. Human tubercle bacilli produce remarkably large amounts of niacin in culture compared with other mycobacteria<sup>1</sup>. The niacin test<sup>2,3</sup>, a biochemical method which differentiates human tubercle bacilli from other mycobacteria, is based on this phenomenon.

Mothes *et al.*<sup>4</sup> and Rio-Estrada *et al.*<sup>5</sup> reported that niacin was formed from aspartic acid by tubercle bacilli, but intermediates in the niacin metabolic pathway, and the nature of the differences in niacin biosynthesis among mycobacteria, are not known.

Recently, Nishizuka and Hayaishi<sup>6</sup> discovered that quinolinic acid was the key intermediate in the biosynthetic pathway of niacin adenine dinucleotide, and free

niacin was excluded as an intermediate in the pathway in rat liver. They also found that this reaction was dependent on 5-phosphoribosyl-1-pyrophosphate (PRPP). Andreoli *et al.*<sup>7</sup> investigated this enzyme activity using *E. coli*. Nakamura *et al.*<sup>8</sup> named the enzyme which catalyses quinolinic acid to niacin ribonucleotide—quinolinate transphosphoribosylase.

The aim of the present investigation was to establish quinolinic acid as a precursor of niacin ribonucleotide in mycobacteria and to define the difference in the activity of quinolinate transphosphoribosylase among mycobacteria. Ten strains of various types of mycobacteria grown on the surface of Sauton's synthetic liquid medium for 3 weeks (one week for rapid-growing and non-pathogenic mycobacteria) were filtered off, and washed three

Fig. 1. Column chromatography of the reaction products of quinolinic acid- $^{14}\text{C}$  with extract of human tubercle bacilli *H37Ra*. The mixing chamber contained 300 ml. of 0.01 N formic acid, followed by 300 ml. of 0.05 N, 300 ml. of 0.4 N and 500 ml. of 2 N formic acid. PA, picolinic acid; NA, niacin; dNMN, niacin ribonucleotide; dNAD, deamido-NAD; QA, quinolinic acid. Added carriers were 2  $\mu\text{moles}$  of niacin, 2  $\mu\text{moles}$  of niacin ribonucleotide, 2  $\mu\text{moles}$  of deamido-NAD and 3  $\mu\text{moles}$  of quinolinic acid.

times with water. Cell-free extracts were prepared by grinding mechanically the washed bacteria with sea-sand and 15 per cent bacterial weight of 'Norit A' was added and centrifuged in the cold at 10,000g for 40 min. The protein content of the extracts was determined by Mehl's biuret method.

First, the quinolinate transphosphoribosylase activity of human tubercle bacilli was investigated using quinolinic acid- $^{14}\text{C}$ . 162  $\mu\text{moles}$  (39,600 c.p.m.) of quinolinic acid- $^{14}\text{C}$  (uniformly labelled except  $\beta$ -carboxyl carbon), 600  $\mu\text{moles}$  of PRPP, 400  $\mu\text{moles}$  of phosphate buffer (pH 7.0) and 100  $\mu\text{moles}$  of  $\text{MgCl}_2$  were added to 2 mg protein of charcoal-treated bacterial extract made from human tubercle bacilli *H37Ra* to give a total volume of 2 ml. which was incubated at 37° for 6 h. After the addition of 0.5 ml. of 5 N  $\text{H}_2\text{SO}_4$ , 32.2  $\mu\text{moles}$  (1,320 c.p.m.) of radioactive  $\text{CO}_2$  were recovered. The reaction mixture was neutralized with saturated  $\text{Ba}(\text{OH})_2$  solution and centrifuged to remove  $\text{BaSO}_4$ . After carriers were added, the reaction mixture was put through a 'Dowex 1'-formate, X-8 column (diameter 0.8 cm, length 29 cm) and was washed with 100 ml. of water. The column was developed by the application of a formic acid concentration gradient<sup>8,9</sup>, and 10-ml. fractions were collected. The results of chromatographic separation were shown in Fig. 1 and Table 1. As seen in Fig. 1, two peaks of radioactivity appeared, which coincided with quinolinic acid as a substrate and niacin ribonucleotide as a reaction product. As seen in Table 1, 24.9  $\mu\text{moles}$  of radioactive niacin ribonucleotide was formed from 162  $\mu\text{moles}$  (39,600 c.p.m.) of quinolinic acid- $^{14}\text{C}$ . No radioactivity was detected in the NAD, niacin and deamido-NAD fractions.

The niacin ribonucleotide fractions recovered were combined and concentrated under reduced pressure at

Quinolinic acid	30,160	23.1	75.9
Total	36,580		92.5

\* The value was calculated from the specific activity of 1 carbon which was one-sixth of that of original substrate.

† The value was calculated from the specific activity per 5 carbons. Five carbons out of the original  $^{14}\text{C}$ -carbons should remain in the products.

25° C. When an aliquot of the solution was subjected to paper chromatography, the radioactivity migrated with an authentic sample of niacin ribonucleotide. The reaction product, niacin ribonucleotide, was further identified by vitamin activity. *Leuconostoc mesenteroides* (ATCC 9135), which utilized only free niacin as a growth factor, was unable to utilize this product as a growth factor but did use the product after alkaline hydrolysis (0.1 N  $\text{NaOH}$ , 100° C, 30 min). Thus, human tubercle bacilli is proved to have quinolinate transphosphoribosylase activity and to convert quinolinic acid to niacin ribonucleotide. The formation of niacin ribonucleotide from quinolinic acid was shown to be PRPP-dependent because no niacin ribonucleotide was formed without PRPP.

Niacin- $^{14}\text{C}$  was tried in the same enzyme system as quinolinic acid, but no radioactive niacin ribonucleotide was formed from niacin- $^{14}\text{C}$ , as detected by chromatographic examinations.

Various strains of mycobacteria were tested for quinolinate transphosphoribosylase activity by the determination of radioactive  $\text{CO}_2$  evolution from quinolinic acid- $^{14}\text{C}$  and by the microbiological assay using *Leuconostoc mesenteroides* after hydrolysis of the reaction mixture. As shown in Tables 2 and 3, human tubercle bacilli have a remarkably high quinolinate transphosphoribosylase activity, about 9–20 times that of other mycobacteria, with the exception of BCG. The enzyme activity of the mycobacteria was proportional to the amount of niacin produced in the culture filtrate.

Table 2. EVOLUTION OF RADIOACTIVE  $\text{CO}_2$  FROM QUINOLINIC ACID- $^{14}\text{C}$  BY THE EXTRACT OF MYCOBACTERIA

Species	Strains	$^{14}\text{CO}_2$ evolved c.p.m.	$\mu\text{moles}$
<i>M. tuberculosis</i>	<i>H37Rv</i>	506	12.4
	<i>H37Ra</i>	432	10.5
<i>M. avium</i>	11755	46	1.0
Photochromogen	p-8	48	1.0
Scotochromogen	p-6	30	0.7
Non-photochromogen	100616	30	0.7

The reaction mixture contained 57.2  $\mu\text{moles}$  of quinolinic acid- $^{14}\text{C}$  (14,000 c.p.m.), 200  $\mu\text{moles}$  of PRPP, 100  $\mu\text{moles}$  of  $\text{MgCl}_2$ , 400  $\mu\text{moles}$  of phosphate buffer (pH 7.0) and 0.5 mg of charcoal-treated bacterial extract in a total volume of 1.5 ml. Incubated at 37° for 6 h.

Table 3. NIACIN RIBONUCLEOTIDE FORMATION FROM QUINOLINIC ACID BY MYCOBACTERIA

Species	Strains	Niacin ribonucleotide formed ( $\mu\text{moles}$ ) Before hydrolysis	After hydrolysis
<i>M. tuberculosis</i>	<i>H37Rv</i>	3	94
	<i>H37Ra</i>	3	91
<i>M. bovis</i>	BCG	1	42
<i>M. avium</i>	11755	0	6
Photochromogen	p-8	0	4
Scotochromogen	p-6	0	10
Non-photochromogen	100616	0	8
Rapid growers	Sato	0	5
Non-pathogenic mycobacteria	<i>M. phlei</i>	0	4
	<i>M. smeg.</i>	0	4

The reaction mixture contained 2  $\mu\text{moles}$  of quinolinic acid, 4  $\mu\text{moles}$  of PRPP, 100  $\mu\text{moles}$  of  $\text{MgCl}_2$ , 4  $\mu\text{moles}$  of phosphate buffer, pH 7.0, and 2 mg of charcoal-treated bacterial extract in a total volume of 3.0 ml. Incubated at 37° for 6 h. Free niacin was determined using *Leuconostoc mesenteroides* (ATCC 9135) before and after hydrolysis (0.1 N  $\text{NaOH}$ , 100°, 30 min) of the reaction mixture.

This investigation was supported in part by research grants from the American Thoracic Society, medical section of the National Tuberculosis Association.

Quinolinic acid- $^{14}\text{C}$  was kindly provided by Drs. O. Hayaishi and Y. Nishizuka, Department of Medical Chemistry, Kyoto University Faculty of Medicine.

COMPARATIVE STUDIES OF AMINO-ACIDS IN SHELL STRUCTURES OF  
*Gyraulus trochiformis*, STAHL, FROM THE TERTIARY OF  
STEINHEIM, GERMANY

By DR. EGON T. DEGENS and STEVEN LOVE

Department of Chemistry and Geology, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts

Fool: Canst tell how an oyster makes his shell ?  
 Lear: No.  
 Fool: Nor I neither: but I can tell why a snail has a house.  
 Lear: Why?  
 Fool: Why, to put's head in.  
*(King Lear, Act 1, Sc. V (Shakespeare))*

SHAKESPEARE'S concept on "Why a snail has a house" has been modified recently. The present consensus on mineralization phenomena in biological systems is that certain organic tissues provide a set of highly specific templates which act as nucleation sites and appear to exercise control over the mode and orientation of the mineral phase. Little is known, however, to account for the wide variation in kind, size and orientation of minerals that are generated by organisms.

Recent biochemical investigations of the organic matrix in bone and shell structures have opened new vistas<sup>1-5</sup>; that is, the arrangement and biochemical composition of mineralized tissues seem to influence both the shell mineralogy and the morphology of the biological species. If these data fall into a pattern, comparative biochemical investigations may reveal interesting details on evolutionary trends in the Earth's history and be used for taxonomic purposes. The objective of the work recorded here is to continue along this line by investigating the development of the organic matrix in the shell structures of a series of perfectly preserved Tertiary freshwater gastropods from the Steinheim Basin, Germany.

The Steinheim *Planorbis* gastropods of the species *Gyraulus trochiformis*, Stahl, are characterized by a unique morphological development of the shell structure. Simple (small-flat) specimens gradually advance into complex (large-high) specimens in relatively short periods of time<sup>6</sup>. This type of alteration has been observed at least twice in the stratigraphical record of the Steinheim Basin sediments. The first sequence investigated starts with the sub-species *steinheimensis* and has its more advanced member in *trochiformis*, whereas the second sequence begins with *oxystoma* and ends with *supremus* (Table 1). Thus *steinheimensis* is the oldest and *supremus* the youngest sub-species of the *Planorbis* series. It should be noted that another sub-species precedes *steinheimensis*, but specimens were not available at the time of the investigation.

The amino-acid analysis involved the following steps: (1) 6 N HCl hydrolysis of the carbonate material at 105°C for 22 h in a nitrogen atmosphere; (2) desalting by ion-exchange resins and elution of amino-acids with 2 N

$\text{NH}_3$ ; (3) chromatographic separation of amino-acids on ion-exchange columns and determination by the ninhydrin reaction, both achieved by the same automatic device<sup>7</sup>: flow rate 70 ml./h and pressure 800 lb./in.<sup>2</sup>. A combined basic-acidic run is accomplished in about 4 h. The carbon dioxide for mass spectrometer analysis is obtained by treating the carbonate with 100 per cent phosphoric acid at 25° C (ref. 8). The isotope data are reported as per mil deviation relative to the PDBI, Chicago belemnite Standards.<sup>9</sup>

Alterations in shell morphology of *Gyraulus* sp. have been interpreted on geochemical grounds to be the result of environmental changes in the sense that a progressive increase or decrease in the salinity of the ancient lake water caused the snails to alter their shell structure<sup>10</sup>. Other organisms, for example fishes, that once populated the Steinheim Lake were presumably less fortunate in adapting to their new surroundings, as they became extinct. Only a few species of *Gyraulus* and some ostracods and algae could perfectly adjust to the new environment; however, judged by the millions of fossilized snails and ostracods, it would seem that the changes favoured these organisms.

The high  $^{18}\text{O}$  content of the shell carbonates reflects a somewhat unusual freshwater environment considering the general low  $\delta^{18}\text{O}$  range for freshwater shell carbonates of about  $-5$  to  $-15$  per mil.<sup>11</sup> The  $^{18}\text{O}$  enrichment in case of the Steinheim specimens must, therefore, mean that prolonged evaporation preferentially removed  $\text{H}_2^{16}\text{O}$  from the ancient Lake leaving a heavy water behind; consequently the concentration of salt must also have increased. Internal (seasonal) variations in the  $^{18}\text{O}/^{16}\text{O}$  ratio of the kind observed earlier in belemnites<sup>12</sup> are also recorded in the *Planorbis* shells; and aragonite is the only mineral form<sup>10</sup>. This attests to the perfect preservation of the fossil material investigated.

The total yield in amino-acids from the shell is rather small (Table 1). On first appearances this feature suggests diagenetic destruction of most of the original organic matrix. The striking resemblance of ancient and recent amino-acid spectra of *Planorbis* sp., however, suggests that one is still dealing with intact proteins. Inasmuch as the organic matrix of the shell structures can be recovered on decalcification as fine, almost transparent, sheets, and furthermore free amino-acids are virtually absent, the second suggestion appears to be true. In summary, it is tentatively concluded that the amino-acids given in Table 1

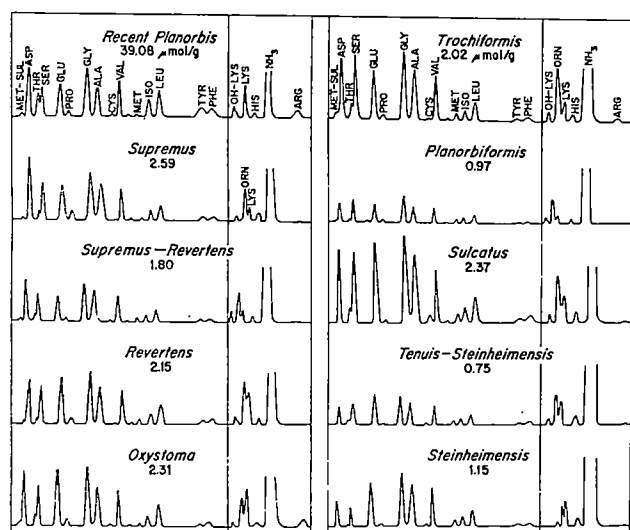

Fig. 1. The amino-acid composition of the organic matrix in shell structures of *Planorbis* sp.

and Fig. 1 represent in close approximation the unaltered building blocks of the original mineralized tissues of *Gyraulus trochiformis*, Stahl. One exception is ornithine, the presence of which appears to be related to the alteration of arginine; it is remarkable, however, that acid hydrolysis is required for the release of ornithine from the organic matrix.

In adopting the customary way of presenting data on amino-acids in mineralized tissues<sup>1,2,4</sup>, the amino-acid values originally calculated on a μmole basis are expressed in amino-acid residues per thousand total (Table 1 and Fig. 1). The isomers of OH-lysine are not included in Table 1, for the area under the peaks could not be reasonably quantitized. It should also be noted that the concentration of the amide amino-acids, that is, glutamine and asparagine, could not be estimated, since the analytical extraction techniques (NH<sub>3</sub>-elution) involved the addition of large amounts of ammonia to the sample.

The neutral amino-acids account for approximately 40 per cent of the total residues; but the ratio of Gly:Ala:Val:Iso:Leu is about the same for all specimens investigated. In contrast, the acidic and basic residues, which respectively amount to 20 and 15 per cent of the total, change in a systematic fashion. While glutamic acid and lysine decrease in abundance from *steinheimensis* to *trochiformis* and again from *oxystoma* to *supremus*, aspartic acid and to a lesser degree the remainder of the basic amino-acids show the reverse trend. The glutamic acid/aspartic acid relationships are plotted in Fig. 2. The loss or gain in residues along the *steinheimensis-trochiformis* profile can be as high as 46 in 1,000 for a single basic or acidic amino-acid. Concerning the rest of the amino-acids, it is only possible at this point to say that the ancient mineralized tissues are generally lower in threonine, tyrosine and phenylalanine than the organic matrix in recent *Planorbis* shell structures; and that proline and sulphur-containing amino-acids exhibit about the same level of concentration for most of the samples investigated.

The following tentative interpretation is offered to account for the amino-acid relationships found in the organic matrices of the gastropod shell structures. Although the primary structure, that is, the specific sequence of amino-acids in the polypeptide chain, cannot be fully delineated at present, it is suggestive that alternating peptide cores, largely consisting of serine, proline and the neutral amino-acids, constitute the molecular framework of the fibrous proteins. Most of the basic, acidic and amide amino-acids, on the other hand, represent the linking residues between one core and the

other. Because the electrical behaviour of proteins and their isoelectric points are determined by the number and location of acidic and basic amino-acids, the special importance of these groups of amino compounds for the problem at hand is well documented. It is conceivable that peptide bonds may open (hydrolysis) at a position where basic, acidic or amide amino-acids confront each other. In consequence, small peptide chains composed predominantly of neutral amino-acids that fall between two such isoelectric points may be eliminated from the matrix. Thus, holes will develop within the protein structure and the now freely exposed acidic or basic amino-acids in the organic residue may concentrate Ca<sup>++</sup> at the acidic side-chains and CO<sub>3</sub><sup>--</sup> at the basic side-chains<sup>2-4</sup>. Nucleation of a mineral phase may proceed inside the holes once an appropriate concentration of the ions has been achieved. Indeed, electronmicrographs of mineralized tissues show a variety of pore patterns that are characteristic for a certain biological species<sup>13</sup>.

In following the scheme outlined, it is finally concluded that the increase in salinity caused the organic tissues in the shell structure to develop a series of additional pores, thereby increasing the number of nucleation sites and decreasing the amount of protein per total carbonate. Thus, some calcified tissues become more effective areas of mineralization than others. It is conceivable that systematic variations in the total amount of organic matter in the shell structure are related to this phenomenon and consequently may be utilized in comparative biochemistry. Inasmuch as the secondary structure of a polypeptide chain and the spacing of the pores will definitely influence the orientation and location of the biogenic minerals, the shell morphology has to change accordingly. Perhaps the alteration of the shell structures as observed in the *Steinheim* specimens is only a consequence of the 'evolutionary' development of the organic matrix and, therefore, a secondary feature. Of particular biochemical interest is also the appearance of hydroxylysine and the absence of hydroxyproline. Both amino-acids are found in mineralized tissues of vertebrates (collagen), but are missing in a number of invertebrates<sup>2</sup>.

Comparative biochemical investigations of mineral tissues tracing, for example, the appearance, disappearance or ratio of amino-acids throughout the plant and animal kingdom may eventually help to outline evolutionary trends in biology and palaeontology, or be of assistance in taxonomic investigations. This can be of special interest in the case of the lower organized groups of organisms (bacteria, foraminifera, etc.), where classifications are frequently based solely on the morphology of the mineralized parts. The relatively high level of acidic and basic constituents in gastropods compared with most other invertebrates so far investigated may explain why they exhibit such a wide variety of shell morphology.

Fig. 2. The aspartic acid/glutamic acid relationships in mineralized tissues of *Gyraulus trochiformis*, Stahl, and the  $\delta^{13}\text{C}$  and  $\delta^{18}\text{O}$  values of the shell carbonate

Finally, if one uses these data as analogy, one perhaps can also tell "How an oyster makes his shell" and thus answer the old Shakespearean question in a more constructive fashion.

We thank Drs. M. Bajor and H. Mensink for contributing sample material and Dr. P. E. Hare for his valuable suggestions concerning improvements in ion-exchange chromatography. The aid of the American Chemical Society and the National Science Foundation is acknowledged (contract 1599).

## GROWTH OF A PRODUCTID SHELL AND ITS IMPLICATION ON A METHOD OF STATISTICAL CORRELATION

By DR. K. A. G. SHIELLS

Department of Geology, University of Glasgow

MARTIN, in his original usage of the word 'productus' in the combination *Anomites productus*, commented directly on the considerably greater length many productid shells have in comparison with their width. The statistical characterization of productid shells in modern investigations always includes, therefore, the measurement of this property, and an important aspect of bivariate analysis is the correlation of the length with the other primary dimensions of the shell. Because of the peculiar shape of the productid shell it is necessary to distinguish between (1) the curved length of the pedicle valve or peripheral distance from umbo to anterior margin; (2) the curved length of the brachial valve or peripheral distance from the hinge-line to anterior margin; and (3) the straight

length from the hinge-line to the anterior margin, all three being measured in the median plane of the shell.

Several authors have noticed a change in growth rate of brachiopod shells during 'old age'—for example, Parkinson in *Dielasma*<sup>1</sup> (pp. 209–213) and *Schizophoria*<sup>2</sup> (pp. 373–376), and Prentice in *Gigantoproductus*<sup>3</sup> (pp. 230–232). The present article attempts to illustrate graphically the character of this alteration in the growth pattern and to demonstrate the necessity of distinguishing the component growth curves before calculating growth ratios. The productid profile used in the figures is that of a new species of marginiferid from the upper Viséan of Scotland, a systematic account of which will be published shortly.

Consider initially a standard plot of the correlation and reduced major axis of, for example, the thickness (height) of the visceral cavity and the curved length of

Fig. 1. Correlation of the curved length of the pedicle valve with the thickness of the visceral cavity. Observed values are shown as dots, the sample mean as an open circle. The reduced major axis gives a growth ratio of 1:3.5

Fig. 2. a, b and c represent three productid profiles; in each, a unit increase in the thickness of the visceral cavity ( $x_1$ ,  $x_2$ ) corresponds to a unit increase in the curved length of the pedicle valve ( $y_1$ ,  $y_2$ ). The growth ratio is 1:3.5 as in Fig. 1. The scatter of the observed data on Fig. 1 would normally be interpreted as the effect of the type of variation in growth form illustrated on Fig. 2. If the growth form of the productid is stable, however, this scatter has another meaning as explained in the text

Fig. 3. The profile of the pedicle and brachial valves of a productid is reproduced identically in *a*, *b* and *c*; the heavy line between the valves is the thickness curve (see text) which is also identical on each drawing. The remaining lines represent a system of co-ordinates to illustrate the growth pattern of the shell. From the intercepts of these lines on each other, on the valves, and on the thickness curve, it is possible to measure the relative increases in the curved length of the pedicle valve, the curved length of the brachial valve, and the thickness of the visceral cavity. In *a*, the variation in the increments of the curved length of the brachial valve and the thickness of the visceral cavity are shown for unit increase in the curved length of the pedicle valve; in *b*, the variation in the increments of the curved length of the pedicle valve and the thickness of the visceral cavity are shown for unit increase in the curved length of the brachial valve; and in *c*, the variation in the increments of the curved length of the pedicle valve and the curved length of the brachial valve are shown for unit increase in the thickness of the visceral cavity.

the pedicle valve (Fig. 1); the measurements are taken from a sample of the population at a single locality. The correlation is good ( $r = 0.917$ ) and the slope of the regression line indicates a growth relationship whereby a unit increase in the thickness of the visceral cavity corresponds to an increment of the curved length of the pedicle valve 3.5 times as great. Using the method described by Prentice<sup>3</sup>, the curvature of the pedicle valve can be analysed in terms of a compound of successive logarithmic spirals. Following this procedure for the sample in question reveals this curvature to be an extremely constant feature of the shell morphology, the sample variation being less than 5 per cent. Assuming, therefore, that variation in curvature of the pedicle valve can be considered to be negligible in this context, it is then apparent that the 1:3.5 growth ratio, here, is not a measure of the average growth ratio for a sample of shells of differing growth forms (Fig. 2) within the total fossil population but a summary of the relative growth of the curved length of the pedicle valve and the thickness of the visceral cavity of any individual of the population. This conclusion enables direct comparison of the growth ratio obtained from the population sample with a growth ratio measured directly from one specimen.

Minimizing the effect of the thickness of the pedicle valve, an accurate median plane profile has been drawn as the basis of Fig. 3. This profile has three variable qualities: (1) the curved length of the pedicle valve; (2) the curved length of the brachial valve; and (3) the thickness (height) of the visceral cavity. It is assumed that the profile of the shell represents a continuous growth form which has not been modified by resorption or addition of secondary accretionary deposits. Such changes may have taken place in the umbonal region, which is consequently omitted from the investigation. From this known profile it is possible to reconstruct an infinite number of previous growth stages by rotating the brachial valve about the hinge towards the pedicle valve and recording points of intersection of the curves of the two valves.

The thickness of the visceral cavity is the maximum separation of the valves normal to tangents of the shell surfaces. As the curvature of the two valves is constant (as opposed to increases in length along these curves) it follows that there must be a third constant curve described by the locus of the point of intersection of the line of maximum thickness with the brachial valve as the brachial valve is rotated. This line is termed the thickness curve and is shown as a thick line in Fig. 3.

Figs. 3*a*, *b* and *c* represent plots of the growth increments of two of the variables for unit increase of the third. From Fig. 3*a* and the graphical representation of the data in Fig. 4*a*, it is clear that for successive unit increase in the length of the pedicle valve the amount by which the brachial valve grows in the same interval of time progressively diminishes to a minimal value approaching the trail. At this point a change in growth rate must have occurred, for subsequent increments of the brachial valve progressively increase to a point lower on the trail. At this second point the parallelism of the brachial and pedicle trails prevents continued growth of the valves at independent rates. Subsequent growth of the two valves is therefore practically equal. Similarly from Figs. 3*a* and 4*c*, it can be seen that for successive unit increase in the length of the pedicle valve the equivalent increments in the thickness of the visceral cavity rise asymptotically to a maximum value which corresponds to a position on the pedicle valve at the junction of the visceral disk and the trail. As in the previous instance a change in the growth pattern then takes place and the subsequent increments of thickness rapidly decrease until the stage is reached in which parallelism of the growth directions of the two valves is achieved. At this point no further increase in the thickness of the visceral cavity is possible without abandoning the curved surface of the trail of the brachial valve. The termination of the growth curve at the point X on Fig. 4*c*, therefore, indicates the position of onset of this ultimate condition in which the thickness remains constant regardless of the extent to which the pedicle valve may grow.

Fig. 3*b* illustrates the variation of incremental values of the curved length of the pedicle valve and the thickness of the visceral cavity corresponding to a succession of equal increases in the curved length of the brachial valve. The growth curves for Fig. 3*b* are complementary to those of Fig. 4*a* and 4*b*, with, in this case, unit increase in the length of the brachial valve plotted on the ordinate axis. Such reciprocal curves show, of course, the inflexions corresponding to the growth-rate changes. As the brachial valve increases in length the corresponding increments in the thickness of the visceral cavity follow a curve complementary to that of Fig. 4*b* but of the type of Fig. 4*c*, that is, rising asymptotically to a maximum value corresponding to the growth stage of the brachial valve where it commences to turn towards the pedicle valve. From this initial change in the growth direction of the brachial valve to the growth stage at which the two valves eventually become parallel there is a rapid decrease in successive expansions of the visceral cavity. After parallelism is reached no further increase in the height of the visceral cavity is possible, but the brachial valve may continue to grow.

Fig. 4. The growth curves *a*, *b* and *c* are graphical representations of data obtained from Fig. 3. In each case, unit increase of one variable has been plotted on the ordinate axis and the size of the corresponding increment of another variable along the abscissa. By adjusting the ascending scales on the ordinate axes so that the bottom of the diagram approaches the origin of growth and the top margin the terminus of growth, it is possible to divide the field into three parts. The lines which thus separate the lower part of the trail, the top of the trail, and the visceral disk, connect points of abrupt change in growth. Growth curve *a* is a plot of unit increase in the curved length of the pedicle valve against the corresponding increments in the curved length of the brachial valve. Growth curve *b* is a plot of unit increase in the thickness of the visceral cavity against the corresponding increments in the curved length of the brachial valve. Growth curve *c* is a plot of unit increase in the curved length of the pedicle valve against the corresponding increments in the thickness of the visceral cavity. The point X on *b* and *c* represents the maximum thickness of the visceral cavity.

The third situation in which unit increments in the thickness of the visceral cavity are plotted against the corresponding extensions of the two valves is shown in Fig. 3c. The growth curve for the relative thickness-brachial valve increments is shown in Fig. 4b. It has an initial asymptotic form corresponding to the progressive decrease in the increments in length of the brachial valve, with a minimal value at the point where the brachial valve commences to turn towards the pedicle valve. A growth-rate change then takes place and the remaining supplements increase to the point X, the maximum thickness of the visceral cavity. The growth curve for the relative thickness of the visceral cavity and the corresponding additions to the length of the pedicle valve is complementary to Fig. 4c and of the curve type of Fig. 4b.

For those productids that do not modify the curvature of the brachial valve, of which the species used in Fig. 3 is an example, a value for the maximum thickness of the visceral cavity can be obtained. Because this value is dependent on the curvature of the two valves, which is almost identical in every individual of this population sample, the maximum thickness of the visceral cavity approximates to an absolute determinant and as such may be of considerable taxonomic importance. In those productids in which the original trail-curve of the brachial valve may be abandoned, by the secretion of overlying layers or by the growth of a diaphragm and new brachial trail, the thickness of the visceral cavity may continue to increase throughout life. In Fig. 5, for example, it can be seen that, if the gap between the trails of the brachial and pedicle valves is widened by supplements to the brachial valve, this has the effect of rotating one valve about the

Fig. 5. Hypothetical profiles illustrating how progressive thickening of the trail of the brachial valve will permit a continual increase in the thickness of the visceral cavity. When the curve of the brachial valve is modified by the first additional layer the thickness curve (long-dashed line) is forsaken; successive increases mark out a 'curve of abandonment' (short-dashed line)

Fig. 6. Part of a growth curve (of the same type as Fig. 4b, but actually complementary to Fig. 4c) showing the variation of increments to the curved length of the pedicle valve for unit increase in the thickness of the visceral cavity. On the right is the frequency distribution of the thickness of the visceral cavity for the sample used to construct Fig. 1. The true relationship between the growth pattern and the sample is shown by the sample area (stippled), a plot of the sample frequency about the growth curve. The regression line from Fig. 1 indicating a growth ratio of 1:3.5 'averages out' the effect of the true change in growth and is therefore not a particularly meaningful construction

hinge relative to the other, thus increasing the thickness of the visceral cavity. The trace of the intersection between the line of maximum thickness and the brachial valve abandons the original thickness curve (Fig. 5, long-dashed line) and as the thickness increases the intersection of the line of maximum thickness with the pedicle valve can be plotted along a 'curve of abandonment' (Fig. 5, short-dashed line). For unit increase in the separation of the original brachial valve from the pedicle valve there is a progressive increase in the corresponding increments in the curved length of the two valves.

It is now clear (Fig. 1) that the correlation based on the total sample data is spurious in that the simple linear function represented by the regression line merely 'averages out' a much more complex growth history. The data of Fig. 1 and Fig. 3c are shown together in Fig. 6. The frequency distribution of the sample variation in thickness of the visceral cavity is plotted about the particular growth curve which illustrates the size of the increments in the curve length of the pedicle valve corresponding to unit increase in the thickness of the visceral cavity. The sample area (stippled) approximates to a dilated parabola and is bisected by the reduced major axis determined on Fig. 1. Thus the value of the growth ratio obtained by the method used to produce Fig. 1 will depend on the shape of the sample distribution curve and the coincidence of this curve with the growth curve. To make an accurate evaluation of the shell growth from sample data it is therefore necessary to reduce the compound growth curve to its component parts and to subject each of these to the standard statistical procedures.

## INDUCTION OF AN ALPHA-GLUCOSIDASE BY GLUCOSE

By DONNA S. HWANG and Prof. CARL C. LINDEGREN

Biological Research Laboratory, Southern Illinois University, Carbondale, Illinois

THE fermentation of melezitose by *Saccharomyces* is controlled by the gene-system *MZ*, which generates a single adaptive enzyme, melezitase. This enzyme is induced by exposure of cells carrying *MZ* to certain

specific alpha-glucosides, namely, turanose (*T*), maltose (*M*), sucrose (*S*), alpha-methyl-glucoside (*G*), melezitose (*Z*) and palatinose (*P*). The enzyme is capable of hydrolysing these same alpha-glucosides<sup>1-3</sup>. A series of multiple

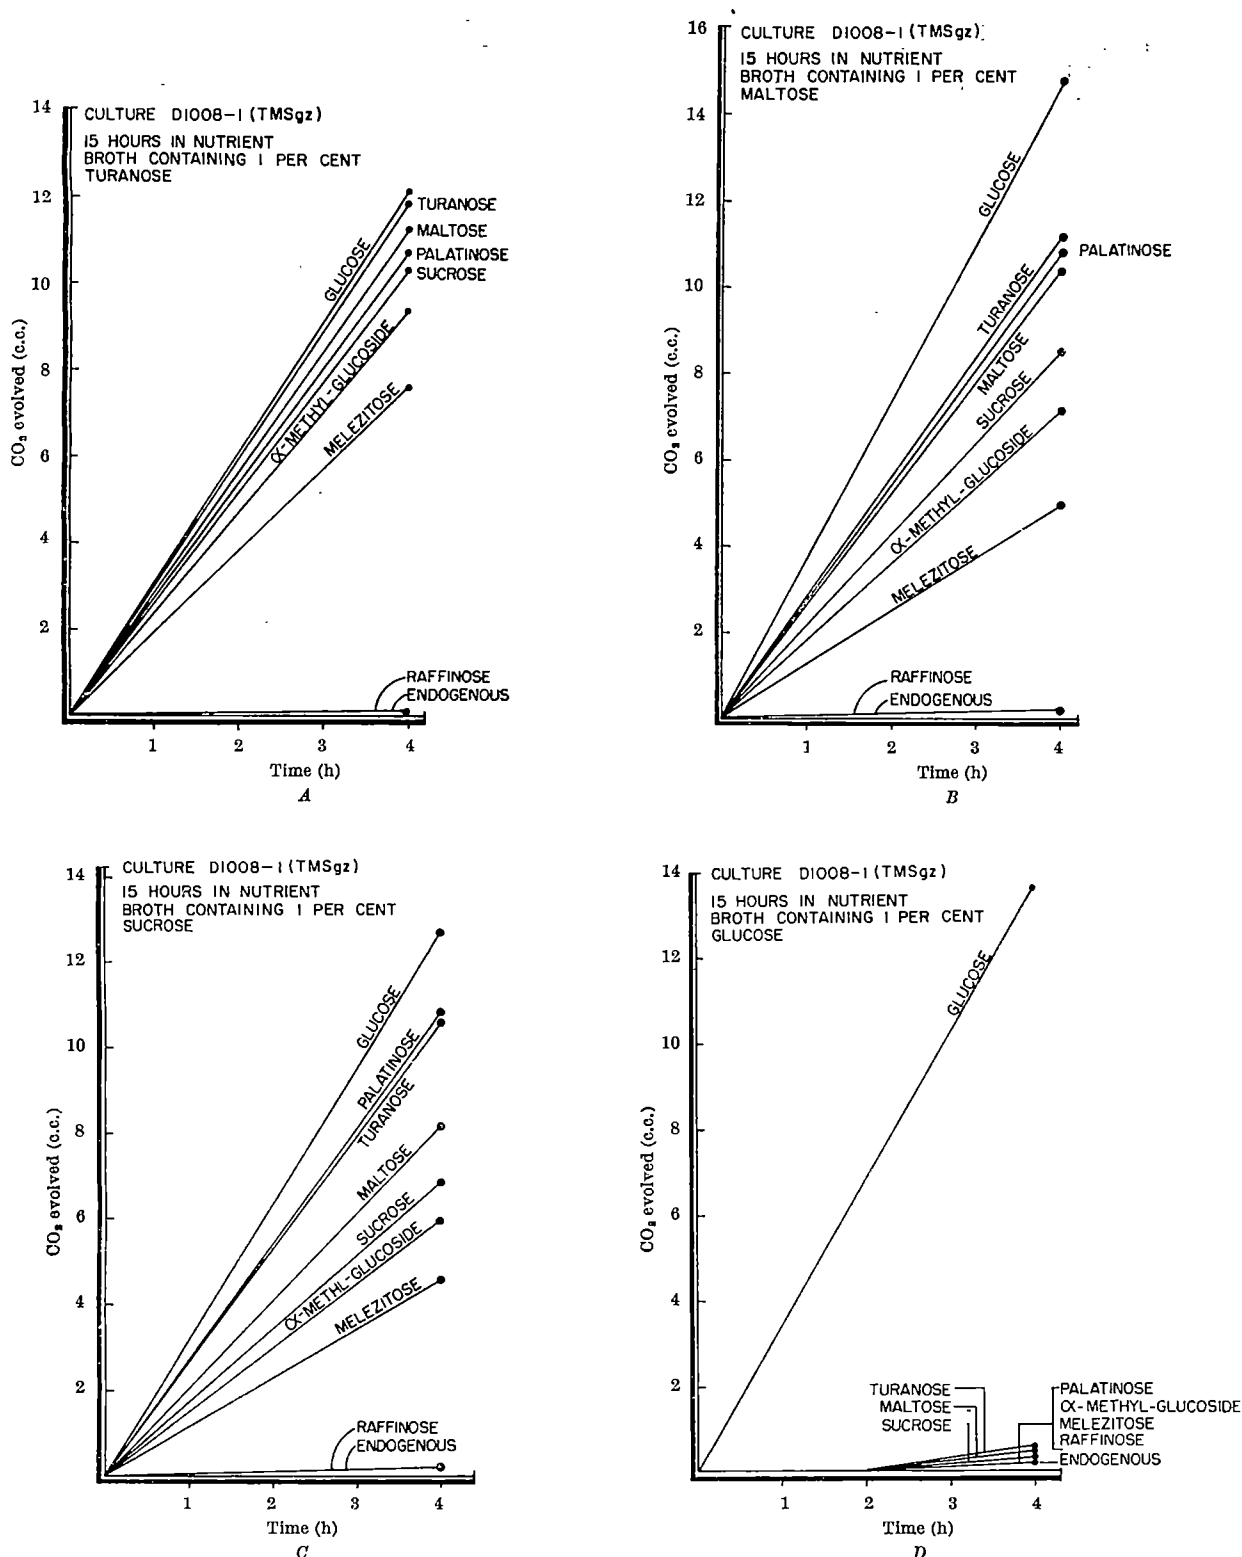

Fig. 1. Culture D1008-1 (*TMSGz*) was grown in 2 per cent glucose nutrient broth for 24 h, adapted for 15 h and tested for CO<sub>2</sub> production on 4 per cent glucose, turanose, maltose, sucrose, α-methyl-glucoside, melezitose, palatinose and raffinose by the syringe gasometer (8 × 10<sup>3</sup> cells in 4 ml. phosphate buffer, pH 4.5 at 30° C)

alleles has been discovered at the *MZ* locus<sup>4</sup>. The allele which elicits enzyme on exposure to all α-glucosides listed here is called 'totipotent', and has been designated *MZTMSGz*, abbreviated to *TMSGz*. Other alleles of the series which differ from one another by their ability to respond adaptively to different α-glucosides have been designated *TMSGz*, *TMSGz*, *TMSGz*, *TMSGz* and

*tmsgz*. (The small letters indicate the inability of a culture to respond adaptively to the respective substrates.)

Cells carrying the *MZ* gene exhibit the phenomena of 'heterologous adaptation' and 'de-adaptation'. In heterologous adaptation, cells incapable of fermenting melezitose become able to do so without lag after exposure, not to melezitose, but to maltose; that is, exposure to maltose

can adapt the culture for the fermentation of melezitose. Adapted cells undergo de-adaptation when the inductor is removed, and de-adapted cells cannot ferment the alpha-glucosides without further adaptation. Cells of the genotype *TMSGZ* (D1008-1) were grown for 24 h under aerobic conditions in broth containing 1 g of  $MgSO_4$ , 2 g of  $KH_2PO_4$ , 2 g of  $(NH_4)_2SO_4$ , 5 g of yeast extract powder, 3.5 g of bacto-peptone and 20 g of glucose in 1,000 ml. of distilled water. The cells were collected by centrifugation. Approximately  $5 \times 10^8$  cells were inoculated into 50 ml. broth containing the components listed here except that it contained 10 g of glucose (control) or 10 g of alpha-glucoside (adaptation) per 1,000 ml. distilled water. The

medium containing the cells was incubated for 15 h on a shaker at 30° C. Both 'control' and 'adapted' cells were collected, and washed three times with  $M/15 KH_2PO_4$ . A total of  $8 \times 10^8$  cells were re-suspended into 4 ml. of the same menstruum containing 4 per cent Seitz-filtered carbohydrate (either turanose, maltose, sucrose, alpha-methyl-glucoside, melezitose, palatinose, raffinose or glucose). The measurement of gas production was made with a syringe gasometer at 30° C (ref. 5). The absence of a source of nitrogen ensured that vegetative growth (budding) did not occur during the measurement of fermentative activity and, hence, that the occurrence of adaptation as indicated by  $CO_2$  production, after a lag

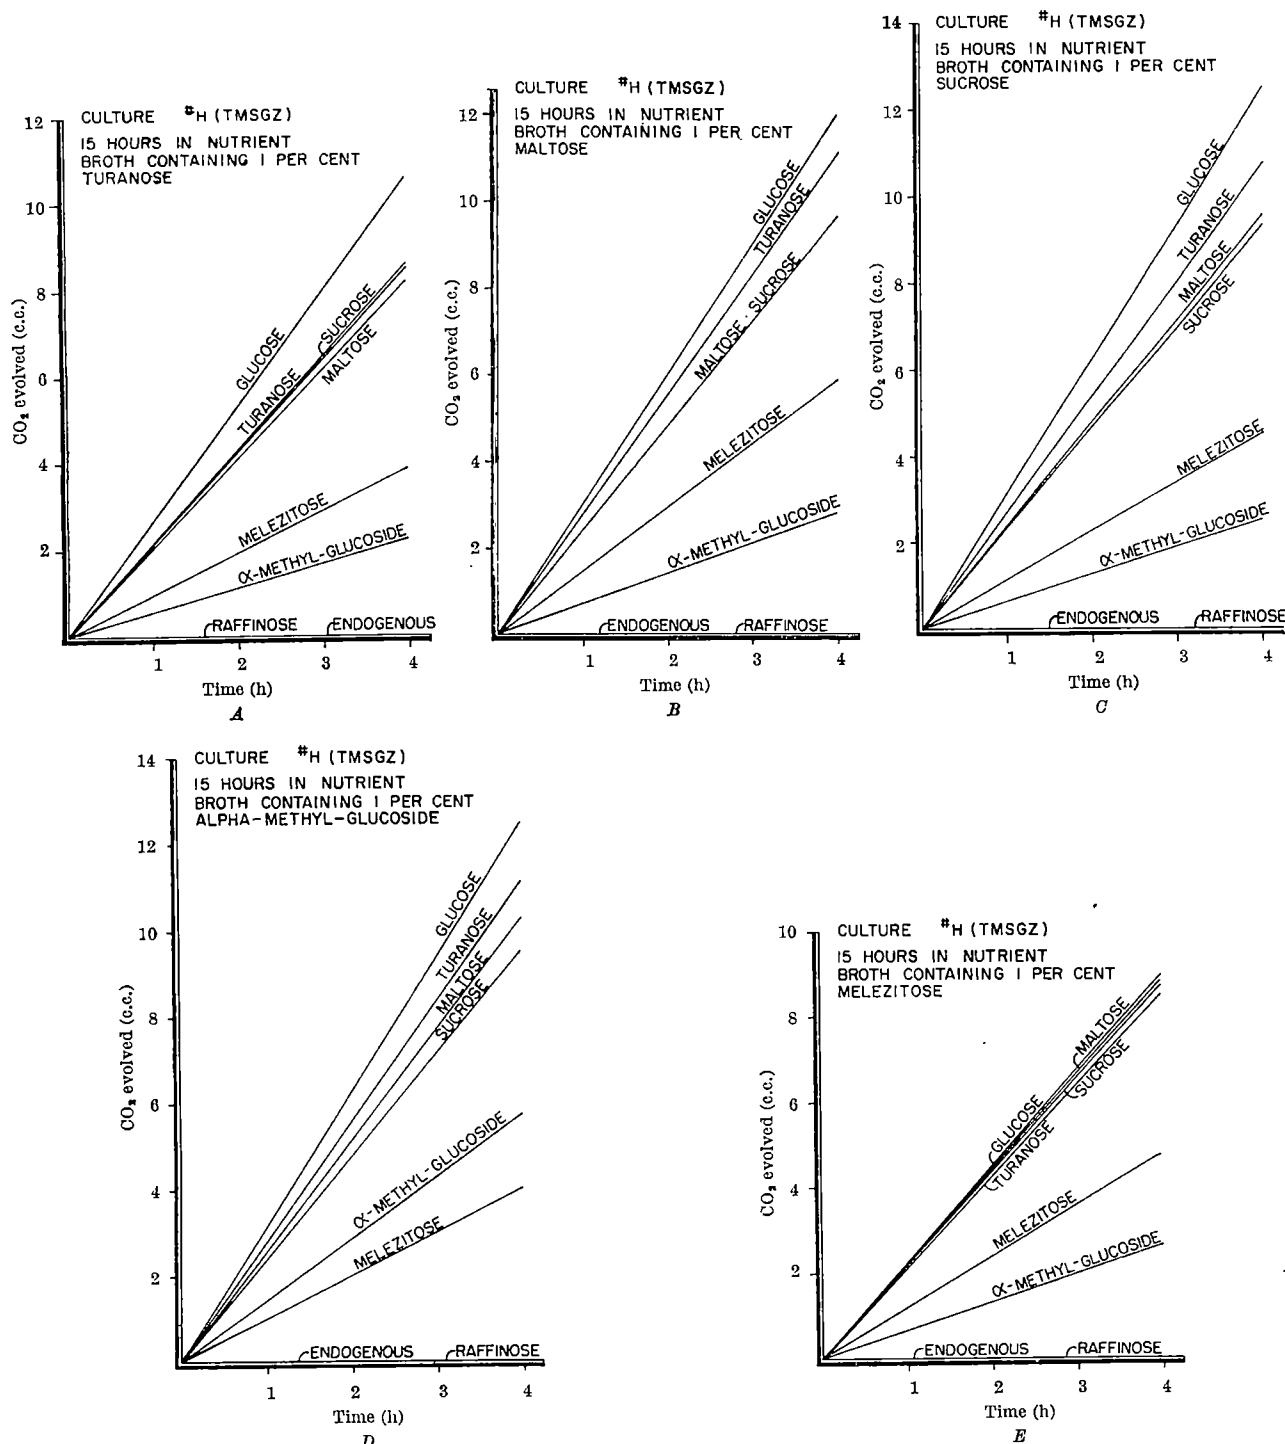

Fig. 2. Culture 'H' (*TMSGZ*) was grown in 2 per cent glucose nutrient broth for 24 h, adapted for 15 h and tested for  $CO_2$  production on 4 per cent carbohydrate by the syringe gasometer under the conditions specified in Fig. 1

Fig. 3. Culture 'H' (TMSGZ) was grown in 2 per cent glucose nutrient broth for 24 h and then exposed to nutrient broth both with and without 1 per cent glucose for 15 h and tested for CO<sub>2</sub> production under the specified conditions (Figs. 1 and 2)

of several hours, was not due to mutation and selection but to adaptation of the total population of cells (presumably by the induction of melezitase). Cells of culture D1008-1 (which were unable to elicit melezitase in response either to alpha-methyl-glucoside or to melezitose) after adaptation to turanose, maltose or sucrose, were able to ferment alpha-methyl-glucoside and melezitose at zero time (Figs. 1A, B and C). The glucose-grown cells of this culture could ferment only turanose, maltose and sucrose, and the fermentation of these sugars occurred only after a lag period (Fig. 1D). The adapted cells underwent de-adaptation after 15 h exposure to a medium without the inductor. De-adapted cells could not ferment alpha-methyl-glucoside or melezitose, but were able to ferment turanose, maltose and sucrose after a lag period.

A totipotent culture 'H' (TMSGZ) was recently obtained by treating an ultra-violet-induced partial mutant, TMsgz, with melezitose which induced mutation from TMsgz to TMSGZ (ref. 6). Cells of this mutant have the characteristics of a totipotent MZ culture, because after they have been adapted either to turanose, maltose, sucrose, alpha-methyl-glucoside or melezitose, they can ferment all these alpha-glucosides without lag (Figs. 2A, B, C, D and E). However, culture 'H' is different from the normal MZ culture because it also ferments all five alpha-glucosides without lag after growth on glucose, without previous exposure to alpha-glucosides (Fig. 3A). One might infer that melezitase was a 'constitutive' enzyme in this culture. But investigation revealed that the activity of melezitase in the glucose-grown cells decreased when glucose was removed from the medium. The longer the cells were exposed to a medium with-

out glucose, the more the enzyme activity decreased. After the cells were held for 15 h in a broth containing all nutrients (described previously) but without glucose, they were unable to ferment either turanose, maltose or sucrose during the first 2 h in the fermentation test, and remained unable to ferment alpha-methyl-glucose and melezitose for 4 h (Fig. 3B). However, when the glucose-grown cells were held in phosphate buffer (pH 4.5) containing 2 per cent of glucose, for 15 h, the enzyme activity was maintained, revealing that melezitase was both induced and maintained by glucose in this particular mutant.

The induction of melezitase by glucose demonstrates the indeterminacy involved in specifying that an enzyme is 'constitutive'. If the inductor is a common and constantly present component of the cell, an inducible enzyme would be mistaken for a 'constitutive' enzyme<sup>7,8</sup>. The induction of an enzyme by one of the 'end-products' of its activity is contradictory to the concept of control by 'feed-back inhibition'.

## AMINO-ACID SEQUENCE OF SPERM WHALE MYOGLOBIN

By DR. ALLEN B. EDMUNDSON\*

Medical Research Council Unit of Molecular Biology, Cambridge

THE circumvention of the problem of the insoluble 'core' by cleavage of the protein molecule with cyanogen bromide<sup>1</sup> made it possible to write an almost

complete amino-acid sequence of sperm whale myoglobin. However, three major tasks remained unfinished: (1) the determination of the sequences in two segments at the amino end of the protein; (2) the alignment of three blocks of sequences in the middle of the molecule; and (3) the

\* Present address: Division of Biological and Medical Research, Argonne National Laboratory, Argonne, Illinois.

Table 1. AMINO-ACID COMPOSITION OF 'CORE' PEPTIDES FROM CM GLOBIN

The compositions of the 'core' peptides are expressed in terms of the molar ratios of the constituent amino-acids. Values for the principal constituents are shown in bold-faced type. With the exceptions of peptides 6 and 7, isolated from a chymotryptic hydrolysate, the peptides were released from carboxymethylated globin by the action of trypsin

\* The *N*-terminal valine residue of this peptide is carboxymethylated, and therefore is not detected during the amino-acid analysis. For details see text.

† Isoleucine is generally not released quantitatively in 48 h of hydrolysis from either peptide 12 or 13, both of which contain the sequence Ala.Ile.Ile.His. In each of these examples the recovery of one residue immediately adjacent to the Ile residues was also low (compare value for *di* CM His in peptide 12 and the Ala value in peptide 13).

The compositions of the peptides in Table 1 indicate that the specificity of trypsin was not rigorously maintained. The aberrant cleavages are identical with those found after hydrolysis with chymotrypsin (compare Fig. 1) and are probably attributable to the manifestation of the chymotryptic activity associated with most samples of trypsin. The chymotryptic-like splits are more readily detected after extended periods of hydrolysis such as those (24 or 48 h) used in this investigation. Furthermore, relatively large quantities of trypsin were used, that is, 2–4 per cent of the weight of globin. In contrast to the results obtained after carboxymethylation, the core regions of the unreacted protein were not susceptible to chymotryptic-like hydrolysis during the exposure to trypsin<sup>9</sup>. The incidence of non-specific splits in the remaining regions of myoglobin was also lower than that for CM globin (Edmundson, A. B., unpublished results). Although the aberrant cleavages complicate the problems of fractionation and the establishment of overlaps, they do provide smaller fragments of what would otherwise be long tryptic peptides unsuitable for direct sequential analysis.

The detection of peptides collectively containing the 12 histidine residues in the form of their 1,3-dicarboxymethyl derivatives indicates that the reaction of bromoacetate with the imidazole groups was probably quantitative. Banaszak *et al.*<sup>2</sup> had previously observed the almost complete disappearance of unreacted histidine under similar conditions. In further agreement with their findings, the  $\epsilon$ -amino groups of lysine residues had not been attacked in any peptides examined (for example, peptides 8 and 10 in Table 1). A comparison of peptide 3 (compare Table 1) with the *N*-terminal peptide, No. 2, showed that the  $\alpha$ -amino group of *N*-terminal valine had been partially carboxymethylated. Peptide 3 was found to be identical in composition with peptide 2 except for the absence of unreacted valine, and to have approximately one more negative charge during ionophoresis at pH 6.4. Moreover, peptide 3 was ninhydrin-negative and did not yield an end group with Edman's phenyl-isothiocyanate method<sup>10–13</sup>. These results suggest that *N*-terminal valine was present in peptide 3, but in the form of its mono-carboxymethyl derivative.

### Chymotryptic Hydrolysis of Myoglobin

In an earlier article<sup>1</sup> the major sites at which myoglobin is hydrolysed with chymotrypsin were indicated in the structural formulae of the products of the cleavage with cyanogen bromide (compare Fig. 3 in ref. 1). The compositions of most of the peptides could be inferred from

this information, but the series had not been completed for the amino end of the protein. Its completion was accelerated by the use of the procedures found to be successful for the purification of similar or identical 'core' peptides from CM globin. The remaining chymotryptic peptides had previously been fractionated by the same general methods, although applied in a greater variety of combinations because of the large number (57) of peptides involved. Because of limitations of space, detailed compositions such as those in Table 1 will not be presented for these peptides, but the principal sites of cleavage are indicated in Fig. 1.

To obtain the long peptides desirable for the establishment of the overlaps, as well as to reduce the complexity of the mixtures to be fractionated, the duration of hydrolysis was at first limited to 3 h, and most of the peptides indicated in Fig. 1 were isolated from this type of chymotryptic hydrolysate. When it became apparent that the 'core' regions in general and the amino-terminal segment in particular were attacked more slowly than the remainder of the protein, the period was increased to 20 h. The latter hydrolysates were used principally for the preparation of larger quantities of peptides from the 'core' regions, and an exhaustive survey of the other components was not undertaken.

The peptide bonds hydrolysed were generally those predicted from the specificity of chymotrypsin—namely, those at the carbonyl ends of tryptophan, phenylalanine, tyrosine, methionine and, to a lesser extent, leucine and histidine (compare sequences given in Fig. 1). Among the unpredicted sites of hydrolysis were those involving such residues as aspartic acid (residue 20; compare Fig. 1), threonine (residues 67 and 70), alanine (residues 90, 94 and 125), glutamine (residues 91 and 128), and asparagine (residue 132). Two minor tryptic-like splits were detected after residues 63 and 77, which are members of highly basic centres with Lys.Lys.His and Lys.Lys.Lys sequences, respectively (compare Fig. 1).

If only unique sequences are considered, the chymotryptic peptides contain a total of 153 residues, identical in kind and number with the composition indicated by the original amino-acid analysis of myoglobin<sup>8,14</sup>. The values obtained<sup>1</sup> for the products of the cyanogen bromide cleavage fell short of this figure by approximately 0.6 of a valine and 0.7 of a glutamic acid residue. It was correctly assumed at that time that the composition of the amino-terminal segment (designated peptide 3 in Fig. 1), should have included an additional valine residue. Now the same conclusion can be applied to the number of glutamic acid residues.

### Identification of the Amides

The asparagine and glutamine residues were distinguished from their acidic counterparts by a combination of the following procedures: (1) paper ionophoresis of appropriate peptides at pH 6.4; (2) quantitative analysis of the amino-acids released from peptides by leucine aminopeptidase or carboxypeptidase A, and/or (3) direct identification of phenylthiohydantoins by the chromatographic techniques of Sjöquist and Edman<sup>11,12</sup>. The results of this investigation, incorporated into the sequence shown in Fig. 1, indicate that only 7 of the 27 possible residues are found in the amide form. This value coincides with that obtained by amino-acid analysis of the intact protein<sup>14</sup>. The ratios of amides to the total number of each type of residue was approximately the same for asparagine and glutamine: 2 (residues 122 and 132) out of 8 were asparagine and 5 (residues 8, 26, 91, 128 and 152) out of 19 were glutamine residues. Of special interest is the fact that 3 of the amides, residues 122, 128 and 132 are concentrated in one region, the last two occupying successive turns on  $\alpha$ -helix H (for nomenclature see ref. 17 and Fig. 1) and the first located in the corner segment between helices G and H. All three are constituents of the peptide Tryp 21 (refs. 8 and 14).

Before the final assignment of the amides in myoglobin it was necessary to consider the possibility of hydrolysis of these groups to their acidic forms. There are three examples of residues (8, 91 and 152) identified as amides in some peptides and as glutamic acid residues in others. This hydrolysis, which fortunately was far from quantitative, could have occurred during the fractionation of the peptides. An alternative explanation, not necessarily exclusive of the first, is based on the chromatographic heterogeneity of myoglobin. The glutamic acid forms of the labile amides were not detected in a 3-h chymotryptic hydrolysate of the principal chromatographic component. They were, however, found in chymotryptic and 'core' peptides from hydrolysates of the protein used without prior separation into five components on 'Amberlite IRC-50' (ref. 14). These results support the suggestion<sup>14</sup> that the chromatographic differences are largely attributable to differences in amide content, and therefore in charge. The three labile amides are in accessible positions, one (residue 91) close to the haem-linked histidine residue and the other two (residues 8 and 152) near the termini, where charge differences would probably be reflected in the chromatographic patterns.

### The Complete Sequence of Myoglobin

If the results in the preceding sections are included, there are now four principal lines of evidence on which the complete sequence of 153 residues can be written. (1) The chymotryptic peptides and (2) the three peptides released by cyanogen bromide contain all segments of the protein. (3) The soluble tryptic peptides together account for 70 per cent of the original molecule, and (4) the 'core' peptides from CM globin represent the remaining 30 per cent. This evidence is summarized in Fig. 1, which is divided into three sections corresponding to the peptides (designated peptides 3, 2 and 1 as in ref. 1) liberated by cyanogen bromide. The numbers of the constituent residues are given and the principal peptide bonds hydrolysed by trypsin and chymotrypsin are indicated by the letters *T* and *C* enclosed in circles. The squares refer to bonds cleaved in the 'core' regions by the action of trypsin on CM globin. The sequences were determined by a combination of the phenyl-iso-thiocyanate procedure and enzymatic end-group methods.

Fig. 1 is largely self-explanatory, and comments about most of the sequence have been made elsewhere<sup>1</sup>. However, the assignment of a few overlaps and the dipeptide sequence at the carboxyl end do require clarification. For example, the compositions given in Table 1 can be used

to determine the alignment of three blocks of sequences in the middle of peptide 2, for which both the *N*-terminal and *C*-terminal segments have already been identified<sup>1</sup>. Peptide 11 in Table 1, with its characteristic tyrosine residue, bridges the blocks marked I (residues 77–103) and II (residues 104–106) in Fig. 3 of ref. 1, and peptides 12–14 link group III (residues 107–115) to the *C*-terminal segment. By elimination, blocks I and II must provide the connexion between the terminal regions. Moreover, group I is the only one of the three to begin with lysine, and the composition of peptide 10 in Table 1 indicates that the *N*-terminal sequence is followed by lysine.

The results of the cyanogen bromide cleavage were used to postulate the approximate formulae of the long tryptic peptides from the 'core'<sup>1</sup>. From the structure of peptide 2, in combination with the compositions of peptides 1–7 in Table 1 and the sequences of chymotryptic peptides indicated in Fig. 1, it is now possible to give the following complete sequences of these fragments:

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Val. Leu. Ser. Glu. Gly. Glu. Trp. Gln. Leu. Val. Leu. His. Val. Try. Ala. Lys															
(peptides 1–8 in Table 1)															
64	65	66	67	68	69	70	71	72	73	74	75	76	77		
His. Gly. Val. Thr. Val. Leu. Thr. Ala. Leu. Gly. Ala. Ile. Leu. Lys															
(peptides 9–10 in Table 1)															
103	104	105	106	107	108	109	110	111	112	113	114	115	116	117	118
Tyr. Leu. Glu. Phe. Ile. Ser. Glu. Ala. Ile. Ile. His. Val. Leu. His. Ser. Arg															
(peptides 11–14 in Table 1)															

The numbering of the residues is identical with that in Fig. 1, and the peptides accounting for the longer fragments are listed after the sequences.

The conflicting results about the dipeptide sequence at the carboxyl end of myoglobin<sup>14,15</sup> have recently been resolved by an investigation of a tripeptide (Tyr, Glu, Gly) released from this region by the action of pepsin. After treatment of the peptide with carboxypeptidase, glycine was the only amino-acid detected in the hydrolysate and has accordingly been assigned the *C*-terminal position. This observation confirms the tentative conclusion<sup>1</sup> that the chymotryptic peptide, Gln.Gly, was also derived from this segment.

The chemical investigation has been carried out in parallel with the determination of the structure by X-ray analysis, and it is of interest to comment on the correlation of the two approaches solely from the point of view of the amino-acid sequence. The three-dimensional structural features observed at a resolution of 1.4 Å and the concomitant interactions of amino-acid side-chains will be discussed in detail by Watson, Kendrew, and their colleagues at a later date. When the resolution achieved by the isomorphous replacement method had reached its limit of 2 Å, Kendrew *et al.*<sup>16,17</sup> were surprised to find that many amino-acid side-chains could be identified. The correlation with the present sequence was good in the segments of the molecule for which the compositions, and in a few cases the sequences, of the peptides were known from the chemical investigation. For the remainder, comprising the insoluble peptides of the tryptic series, only approximate overall compositions were available, and the 1:1 correspondence was understandably less precise. The comparison also indicates that the crystallographic identifications proved most difficult in the non-helical regions of the polypeptide chain.

Because of its high helical content (75–80 per cent), low molecular weight (17,816), and absence of disulphide bonds, myoglobin at present appears to be the most suitable protein for X-ray analysis. Even in this case, however, the experience of Kendrew *et al.* has indicated that the data must be extended to atomic resolution (less than 1.5 Å) before unequivocal sequences can be derived by X-ray analysis. Now that the positions of more than 90 per cent of the non-hydrogen atoms have been assigned, the agreement is complete in all these cases. Since the X-ray diffraction data from proteins seldom extend beyond 2 Å, it seems probable at present that the sequence information in most crystal investiga-

tions will have to be deduced by chemical methods and used by the crystallographer in the interpretation of his structural results.

I thank Mrs. Margaret Ross, Miss Pauline Sorrell and Miss Jean Parkinson for their help; Drs. J. C. Kendrew and Dr. H. C. Watson for their continued interest and support; Dr. L. J. Banaszak and Dr. F. R. N. Gurd for advice, particularly in the use of bromoacetate; the Medical Research Council for furnishing facilities and supplies; and the U.S. Public Health Service for provision of a fellowship and an amino-acid analyser (grants Nos. A-3032 and A-3032 (S1)).

## LYMPHOCYTE FOOT APPENDAGE: ITS ROLE IN LYMPHOCYTE FUNCTION AND IN IMMUNOLOGICAL REACTIONS

By DR. WILLIAM MCFARLAND and PROF. DOROTHY H. HEILMAN

Veterans Administration Hospital and Georgetown University School of Medicine, Washington, D.C. 20007

**B**LAST-CELL transformation and mitotic activity result when peripheral blood leucocytes from unrelated individuals are cultured together<sup>1</sup>. In order to observe the cellular interactions involved we used time-lapse photography to follow events in single donor and mixed cultures prepared without the addition of extraneous materials such as phytohaemagglutinin, heterologous serum or antibiotics. In the course of this investigation we observed a unique kind of attachment between lymphocytes and other cells. Lymphocytes appeared as anatomically polarized units with a foot appendage capable of firm attachment to the surface of cells or to cell debris. This method of sustained contact was different from 'peripolexis', the free movement of lymphocytes around the perimeter of a cell<sup>2</sup>, or the entry of lymphocytes into living cells and their wandering about, to which Pulvertaft has given the name 'emperipolexis'<sup>3</sup>. Although the attachment of lymphocytes to other cells was observed in cultures of leucocytes from a single donor, this activity was striking in mixed leucocyte cultures.

Venous blood containing 0.02 mg/ml. of heparin was allowed to settle for 1-2 h, and the cell-rich plasma was removed. The remainder of the specimen was centrifuged at 3,000 r.p.m. for 30 min to obtain additional plasma. The leucocyte-rich plasma was diluted with an equal volume of culture medium TC 109, and placed in large T-flasks for 20 min to allow polymorphonuclear leucocytes to attach to the glass. Cultures were placed in Carrel flasks and consisted of 3 ml. TC 109, 2 ml. plasma and approximately  $1.0 \times 10^6$  leucocytes per 5 ml. culture. Control cultures contained cells and plasma from a single donor, whereas in mixed cultures half the cells and plasma were furnished by each of two unrelated donors. Observations were made with an inverted phase microscope enclosed in a 37°C incubator, and fitted with a 16-mm time-lapse ciné camera. We observed cultures continuously for 6 days, and alternately photographed control and mixed cultures. At 12-h intervals a control and a mixed culture were centrifuged at 600 r.p.m. for 10 min and some of the sedimented cells were placed between 2 large No. 2 coverslips (43 × 50 mm and 22 × 40 mm). Thin cultures were sealed and observed continuously for 4-5 h. Remaining cells from each specimen were spread on coverslips as for routine blood films and stained with Wright and Giemsa stains.

During the first 24 h control and mixed cultures were similar in that polymorphonuclear leucocytes degenerated progressively and macrophages became more conspicuous

(Fig. 1A). A few lymphocytes firmly attached to other cells by means of the foot process, but such attachments were usually for short periods, rarely longer than an hour. This brief interaction between lymphocytes and other cells remained the only characteristic of control cultures during the entire 6 days of culture. Emperipolexis was not seen and no blast cells were present at the end of the culture period.

Mixed leucocyte cultures, however, contrasted sharply with controls after the first day (Fig. 1B and C). Lymphocytes tended to gather in the vicinity of macrophages and demonstrated peripolexis and emperipolexis. Time-lapse investigations showed rupture of occasional macrophages as a result of emperipolexis. On day 2 many lymphocytes were firmly attached to macrophages by means of their foot appendages, the attachment remaining fixed in spite of vigorous cell motions. Sometimes clumps of 10 or more lymphocytes were attached in a radial

fashion to macrophages (Fig. 1D). On day 3 a few of the lymphocytes attached to macrophages began to transform and appeared several times larger than surrounding lymphocytes. An examination of fixed, stained cells from mixed cultures at 72 h showed that blast cells constituted 0.9 per cent of surviving lymphocytes. On day 4, transforming cells were recognizable by their increased size, and lymphocytes immediately surrounding them began to enlarge. Interaction between lymphocytes was observed frequently (Fig. 1E). On days 5 and 6 occasional transformed cells detached from macrophages, and as they migrated into the medium several small lymphocytes promptly attached themselves to the foot process of the blast cell (Fig. 1F). Mixed cultures stained on day 6 contained 0.2 per cent of cells in mitosis and 10.8 per cent transformed cells.

On high-power phase microscopy, the long, slender foot appendage appeared to end in a burr-like process that

contained a number of granules. Thread-like extensions projected from the end of the appendage forming a flexible connexion between the lymphocyte and other cells.

Efforts to obtain electron micrographs of the lymphocyte foot appendage in mixed leucocyte cultures were encumbered by the relatively low rate of blast transformation. Accordingly, for this phase of our investigation we examined sections of ordinary phytohaemagglutinin-stimulated leucocyte cultures in which the rate of blast transformation is high and lymphocyte foot appendages are a common phenomenon in our experience. Fig. 2A shows the foot appendage on a typical cell and Fig. 2B shows the delicate, finger-like projections.

Although the lymphocyte has long been recognized by its characteristic 'hand mirror' configuration, no functional significance has been attributed to the 'handle' of the 'hand mirror'. In this investigation it appeared as a specialized organelle by which lymphocytes attached to macrophages and other cells. It seemed to be part of a normal process which probably also occurs *in vivo*. Schoenberg *et al.*<sup>4</sup> have demonstrated a direct cytoplasmic connexion between lymphocytes and macrophages. Whether a cytoplasmic connexion exists through the foot process is not known; however, this specialized mode of attachment would seem to serve some purpose in lymphocyte function. The prolonged attachment to degenerated leucocytes suggested the possibility of absorption of products of autolysis, and another possible reason for the appearance of lymphocytes in an area of inflammation after the early emigration of leucocytes. Contact between lymphocytes could provide a method of transfer of RNA and other nucleic acids and materials without the necessity of cell division and death. Such an exchange would explain the prolonged retention of labelled nucleic acids in circulating lymphocytes<sup>5</sup> and obviate the necessity of postulating extreme longevity on the part of some lymphocytes<sup>6</sup>. Passage of instructive material on sustained contact between lymphocytes would provide a possible means of maintaining antibody-forming capacity for many years without the persistence of antigen in tissues.

The close association between macrophages and transforming lymphocytes was in agreement with the description of the immunological unit by Thiery<sup>7</sup> and Fishman's demonstration of the role of the macrophage in primary antibody reactions<sup>8</sup>. In our experiments only a small proportion of lymphocytes transformed initially. This evidence of heterogeneity was in accordance with the views of Burnet<sup>9</sup> and the *in vitro* results of Jerne and Nordin<sup>10</sup>. Events we recorded early in blast formation strongly suggested the transfer of stimulatory material from transformed cells to lymphocytes. This would provide an alternative method in addition to mitotic division for the development of islands<sup>11</sup> or 'clones'<sup>9</sup> of antibody-forming cells in the tissues of animals after primary antigenic stimulation. The extent of actual transfer must be determined experimentally, but the specialized mode of lymphocyte attachment seen in normal cultures and accentuated in 'stimulated' cultures points to the probability that this phenomenon plays a part in lymphocyte interactions in normal and pathologic states.

## ASTROPHYSICS

### Origin of $\text{NH}(A^3\Pi) \rightarrow \text{NH}(X^3\Sigma^-)$ Emission in Comets

THE presence of NH radicals in the coma of comets has been generally attributed to photodissociation of ammonia. However, vacuum ultra-violet photolysis<sup>1</sup> (1236 Å) of ammonia results in emission at 3240 Å:

while the cometary emission at 3360 Å corresponds to:

The energy-level diagram for NH showing the position of the states and the transitions under discussion is shown in Fig. 1. In the vacuum ultra-violet flash photolysis of ammonia<sup>2,3</sup>, the NH absorption band at 3360 Å ( $A^3\Pi \leftarrow X^3\Sigma^-$ ) was observed.

These results may be explained<sup>3</sup> by initial formation of NH in the singlet system:

with collision-induced transformation to ground state NH.

Ground state NH could also be formed directly in decomposition of  $\text{NH}_3$ :

Formation of  $\text{NH}(X^3\Sigma^-)$  and  $\text{H}_2$  is spin forbidden since the excited state of  $\text{NH}_3$  formed on absorption of light in the region 1220–1440 Å (state III) is a singlet<sup>4</sup>. Whatever the mechanism for production of ground state NH, it is evident that in photodecomposition of ammonia, NH is formed to some extent in the singlet system. Since the  $a^1\Delta \rightarrow X^3\Sigma^-$  is highly forbidden,  $\text{NH}(a^1\Delta)$  will have a long lifetime in absence of collision with other molecules. Evidence for the fact that radicals do not suffer collisions from the time of their formation near the nucleus until resonance fluorescence occurs further out in the coma comes from the observation that the  $\text{C}_2$  radical shows a vibrational and rotational distribution, which corresponds to a temperature of about 2500° K, while CN simulates

a very low-temperature distribution. A completely symmetrical molecule like  $\text{C}_2$  has no permanent dipole and is therefore unable to emit vibrational and rotational energy. Energy may therefore be transferred only by collisions. The fact that  $\text{C}_2$  retains excess vibrational and rotational energy suggests that it has suffered few, if any, collisions from the time of its formation to the time of its excitation by a fluorescence process. Thus in the coma of a comet, considerable concentration of  $\text{NH}(a^1\Delta)$  should accumulate if ammonia is the source of NH radicals. Emission from  $\text{NH}(c^1\Pi)$  at 3240 Å by a fluorescence process should be observed in cometary spectra along with the 3360 Å emission from the triplet system of NH. Since only the 3360 Å emission is observed, an alternative source of NH radicals which produces only the triplet system on photodecomposition is required.

Recent results obtained in our laboratory on emission spectra from hydrazine vapour during photolysis at the krypton resonance lines (1236 Å and 1165 Å) are pertinent to this problem. While the work was in progress, Becker and Welge reported<sup>5</sup> results on the emission spectra during photolysis of hydrazine which are in complete agreement with our observations. When hydrazine, carefully purified of ammonia, is photolysed at 50  $\mu$  mercury pressure, emission at 3360 Å is observed. This is undoubtedly the 0,0 band of the  $A^3\Pi \rightarrow X^3\Sigma^-$  NH transition. Emission is not observed at 3240 Å (0,0 band of the  $c^1\Pi \rightarrow a^1\Delta$  transition). Detection of emission at 3240 Å in presence of emission at 3360 Å is within the resolution of our grating, and emission at 3240 Å amounting to a few per cent of that at 3360 Å could have been detected. Thus photodecomposition of hydrazine appears to produce NH radicals in the triplet system only. On this basis we would suggest that the immediate precursor of NH radicals in comets is hydrazine or a hydrazine-type molecule and that the role of ammonia in the comet model needs reconsideration.

## RADIOPHYSICS

### Dependence of the Critical Frequency of the Ionospheric E-layer on Solar Zenith Angle and the Annual Variation in E-layer Ionization

It is generally known that  $f_oE$ , the critical frequency of the ionospheric E layer, varies in a fairly regular manner with a law of the form:

$$f = f_o \cos^{\lambda} \chi \quad (1)$$

where  $\chi$  is the solar zenith angle. This form can be applied to both diurnal and annual variations, and generally both  $f_o$  and  $n$  are different for these two variations. To distin-

Fig. 1. Energy-level diagram of NH

guish these two cases we use  $f_a$  and  $m$  for diurnal variations, and  $f_a$  and  $n$  for annual variations. It is known that  $m$  is greater than  $n$  except at stations in equatorial regions and at very high latitudes (see Fig. 1), while  $f_a$  is greater than  $f_a$  everywhere<sup>1</sup>.

There is another variation in  $f_oE$  with  $\chi$ : for a fixed local time (for instance, noon) at a fixed season,  $\chi$  has a variation with latitude; therefore, for a variation in  $f_oE$  accompanying this latitudinal variation in  $\chi$  we can write:

$$f = f_l \cos \chi \quad (2)$$

Values of  $f_l$  and  $l$  can be determined by using data from stations distributed in latitude.

Minnis<sup>2</sup> has argued that both  $f_a$  and  $f_a$  are not, in a strict sense of the word, the critical frequencies at the 'sub-solar point'. Applying (1) to a single station, we have no observed value of  $f_oE$  at small solar zenith angles except at stations at latitudes less than  $23.5^\circ$ ; therefore, the extrapolation of a series of observed values to a hypothetical condition  $\chi = 0$  is quite unreliable. It must, however, be noted that one can obtain an accurate value of  $f_oE$  at the sub-solar point by applying (2) to a series of noon  $f_oE$  observed for various stations. In this case, we always have a station not far from the sub-solar point; therefore, this short extrapolation can give a reliable estimate of  $f_oE$  at the sub-solar point.

It is also argued by Minnis that the marked annual variation in  $f_oE$  could be explained by the relation:

$$f_a = f_a \sec^{(m-n)} \chi_{\text{noon}} \quad (3)$$

The winter value of  $f_a$  is greater than the summer value because of the greater value of  $\chi_{\text{noon}}$  in winter. In this argument Minnis seems to discuss the seasonal component of variations and to attribute its origin to the fact that  $m > n$ . This could be another aspect of the fact that the winter value of  $f_oE$  is greater than the summer value for the same value of  $\chi$ , which was discovered and called the 'seasonal anomaly' by Appleton<sup>3</sup>. Since  $m$  varies very little between summer and winter<sup>1</sup>, the diurnal curve of  $f_oE$  plotted against  $\chi$  has almost the same slope for summer and winter. For annual variations, the data for smaller (or greater)  $\chi$  are contributed from the summer (or winter) observations; therefore, they give smaller (or greater) values of  $f_oE$  than the corresponding value in winter (or summer). Thus, the annual curve has a lower slope than the diurnal curve and from this it results that  $m > n$ .

It must be noted, however, that at equatorial stations such as Huancayo ( $12.0^\circ$  S. in geographic latitude) and Trinidad ( $10.6^\circ$  N.)  $m$  is smaller than  $n$  as is seen in Fig. 1, which is plotted from Table 1 of the review article by Robinson<sup>1</sup> and also includes the data by Minnis. This result cannot be explained by the 'seasonal anomaly' and

Fig. 2. Schematic illustration of the distribution of  $f_oE$  versus  $\chi$ , the solar zenith angle, for non-equinoctial months

it may suggest that the annual component of variations exceeds the seasonal component at low latitudes. It is reported<sup>2</sup> that at Lwiro ( $2.3^\circ$  S.) and Nha-Trang ( $12.0^\circ$  N.) the seasonal component of variations in  $f_a$  is less than one-tenth of that at Lindau ( $52.0^\circ$  N.) and Freiburg ( $48.0^\circ$  N.).

It is important to distinguish between the two facts that  $f_oE$  is greater in local winter than in summer for the same value of  $\chi$  at middle and high latitudes (about  $20^\circ$  to  $60^\circ$ ) and that  $f_oE$  at the sub-solar point is greater in December than in June. The former is a seasonal effect and may be explained by the fact that the maximum point (the axis of the symmetry) of  $f_oE$  versus  $\chi$  distributions is shifted from the sub-solar point ( $\chi = 0$ ) toward the equator. This was found by Appleton, Lyon and Turnbull<sup>4</sup> and myself<sup>5</sup> and is perhaps partly due to the vertical drift effect of the overhead  $S_q$  current system and the seasonal difference of its current intensity<sup>6,7</sup> and partly to a seasonal variation in the upper atmospheric parameters, such as temperature, temperature gradient, and composition. By comparing the point A with B in Fig. 2, which illustrates schematically the distribution of  $f_oE$  versus  $\chi$  in non-equinoctial months, we can easily see that the winter value is always greater than the summer for the same value of  $\chi$ , say  $40^\circ$ .

On the other hand, the latter fact is concerned with the world-wide component of variations in the E-layer ionization. The sub-solar value indicated by C in Fig. 2 may have some seasonal variations, but most of its variation is certainly due to the annual component of variations, because the sub-solar point is always in the summer hemisphere (or at the equator) and never in the winter hemisphere.

In previous papers<sup>5,8</sup> I tried to clarify the characteristics of the world-wide (non-seasonal) component of variations. For this purpose only sub-solar conditions were considered so that the seasonal component might become very small. The result that  $f_oE$  at the sub-solar point is greater in December than in June may be partly explained by the effect of the annual variation in Sun-Earth distance, but the observed variations are slightly larger than what can be attributed to this effect alone<sup>9</sup>. Thus, it is not possible to exclude entirely the possibility that there is a small annual component of variations in the E-layer ionization due to some unknown causes. Minnis stated that my previous result required an additional 'winter' ionizing agency. Actually, however, an additional electron density is needed in December solstice for the whole world.

In Fig. 1 it can also be seen that the indices  $m$  and  $n$  are very small and that  $m < n$  at stations at latitudes higher than about  $55^\circ$ . These are additional anomalies and may suggest the existence of some additional ionization at high latitudes, which has a slower variation with

Fig. 1. Latitudinal dependence of the diurnal ( $m$ ) and seasonal ( $n$ ) indices in  $f_oE = f_a \cos^m \chi$  or  $f_oE = f_a \cos^n \chi$

than that given by (1), although attention must be directed to the fact that the determination of indices is seriously affected by possible errors in the observations of  $\epsilon_0 E$  at high latitudes because such data are restricted to large values of  $\chi$ .

## GEOFYSICS

### Satellite Geoid and the Structure of the Earth

PROF. EGYED postulates<sup>1</sup> that harmonics of low degree of the geopotential arise from undulations of the core-mantle interface, and argues that the correspondence between highs and lows of the geoid surface and the isoporic foci of the vertical component of the geomagnetic field support this view. This argument is surely untenable. First, the correlation between magnetic and gravity fields is weak. This may be shown using either of Izsak's geoids<sup>2,3</sup> and the secular variation of the vertical (Z) or the eastward horizontal (Y) components of the geomagnetic secular variation field for the epoch 1942.5, given by Vestine *et al.*<sup>4</sup>. Values of the geoid heights and the magnetic field components were taken at corresponding 10° intervals. A weak correlation exists between the Y-components and the 'old' geoid but no correlation between any of the others:

Correlated variables	Correlation coefficient
Izsak's old and Z	+0.19749
Izsak's new and Z	-0.00536
Izsak's old and Y	+0.51797
Izsak's new and Y	-0.01935

Only the Z and the Y isopores were chosen because all other geomagnetic maps, whether isoporic or not, do not correlate as well.

Secondly, it does not seem possible to explain the 200 km high corrugation, which Egyed suggests in the core-mantle interface, by variation of chemical composition or temperature differences. As the density difference between the mantle and the core is 4 g/c.c., this undulation implies stress differences of  $10^{11}$  bars, greater than the breaking stress of iron or silicates at ordinary temperatures. If the phenomenon exists, the mechanism must be a hydro-magnetic one. The magnetic field at the Earth's surface may only be a weaker secondary field and the toroidal field threading and sustaining these undulations may be much greater. Equating the magnetic and hydrostatic pressures and assuming a density difference,  $\rho$ , of 4 g/c.c., a value for  $g$  of  $981 \text{ cm/sec}^2$  and a value of the undulations' height  $h$  to be  $2 \times 10^7 \text{ cm}$ , then:

$$H = \sqrt{\rho gh 4\pi} \approx 10^6 \text{ oersteds}$$

This value of the toroidal field at the core-mantle boundary is four orders of magnitude greater than those assumed by Bullard and Gellman<sup>5</sup> in their dynamo theory of the field. There is, however, a third and fatal objection to Prof. Egyed's idea.

The geomagnetic field drifts westwards at an average rate of  $1/5^\circ$  per year. Prof. Egyed's hypothesis must mean that the gravity anomaly is also rotating at the same rate of  $30^\circ$  every 150 years. The width of the gravity anomalies is of the order of  $30^\circ$ , so that the geoid surface must rise or fall by 30 m every 150 years. If the mantle is rigid over this short time scale, then this must mean that the ocean-levels change by about 50 m. As there is certainly no such recorded anomalous 'tidal' phenomenon, which, of course, would have flooded major cities, it must be concluded that the geoid does not drift.

In conclusion, the gravity anomalies of low degree arise from density differences in the mantle and it has been shown<sup>6</sup> that these are likely to arise from convection currents and, as a result, it does not seem possible to relate the geoid with the core-mantle boundary.

<sup>6</sup> Runcorn, S. K., *J. Geophys. Res.*, **69**, 4389 (1964).

THE aim of my article was to show that the theoretical result derived by Cook<sup>1</sup> (that the low-degree harmonics of the geopotential originate from the area of the core-mantle boundary) is in accordance with the results obtained by the reflexions of seismic waves from the core-mantle interface showing undulations of  $\pm 200 \text{ km}$  (ref. 2). It was shown also that the order of magnitude of geoid undulations corresponds to the gravity effect of the core undulation.

It was also mentioned that there is a correlation between the distribution of isoporic foci of vertical magnetic intensity and the geoid undulations, a positive centre being found always in the neighbourhood of a positive geoid height, and a negative centre in the vicinity of a geoid depression. This was valid except as to the geoid depression of Antarctica. Prof. Runcorn's remark, that the correlation became worse in the case of the new Izsak-geoid, is true. This can be interpreted, however, according to the results of Cook, in the sense that the

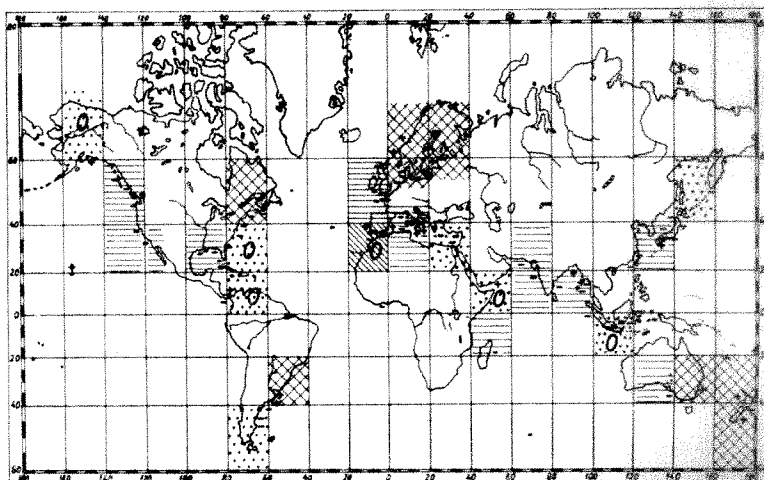

Fig. 1. Correlation between the vertical coastal movements and the satellite geoid, according to the data of Izsak and S. Polli. Cross-hatching, positive geoid undulation with uplifting coasts; horizontal lines, negative geoid undulation with sinking coasts; diagonal lines, no undulation and no change in the coast levels; dotted areas, contrasting undulations and coastal movements (zero undulations contrasting with positive or negative coastal movements are indicated by 0).

higher-order harmonics are affected first by the masses lying on higher level.

I agree with the second remark—and this is mentioned in my article—saying that the core-undulations cannot be explained by variations of chemical compositions or temperature effects. No difficulty arises, however, if the core is a high-pressure-phase transition of the mantle material only.

In my opinion the third objection is not serious. In the case of the tidal phenomenon also the Earth cannot be considered as rigid. It is still less rigid for a time interval 50,000 times longer.

It is remarkable that there is a correlation, not strong, but positive, between the vertical crustal movements<sup>2</sup> of the coasts and the satellite geoid. This contradicts an explanation by convection currents (Fig. 1).

## PHYSICS

### Relativistic (Non-Linear) Oscillator

THE equation of motion of the relativistic oscillator (without damping):

$$\frac{d}{dt} \left( \frac{m_0 \dot{x}}{\sqrt{1 - \dot{x}^2/c^2}} \right) + kx = 0 \quad (1)$$

has been solved in terms of elliptic functions<sup>1</sup>. The result shows the frequency to decrease with the total energy, but does not make explicit how it is related to the amplitude of oscillation. A formula which is more amenable to experimental test is obtained when we approximate the original equation by:

$$\begin{aligned} \ddot{x} + \omega_0^2 x - \varepsilon x \dot{x}^2 &= 0 \\ \varepsilon &= \frac{3}{2} \frac{\omega_0^2}{c^2} \text{ and } \omega_0^2 = \frac{k}{m_0} \end{aligned} \quad (2.1)$$

It is found, then, that the frequency shows a red-shift:

$$\frac{\Delta\omega}{\omega} = -\frac{\varepsilon A^2}{8} \quad (3)$$

where  $A$  is the amplitude of oscillation. This result agrees with that derived by another method<sup>2</sup>.

The equation of motion of the relativistic oscillator (with damping) is, approximately:

$$\ddot{x} + \omega_0^2 x + b\dot{x} - \varepsilon x \dot{x}^2 = 0 \quad (4)$$

where  $b = \frac{\gamma}{m_0}$  and  $\gamma$  is the damping coefficient. The same red-shift occurs, in first approximation. However, the new frequency is quickly damped out so that this oscillator exhibits the linear frequency  $\omega_0$  (ref. 3).

Similarly, the equation of motion of a relativistic oscillator (without and with) damping which is driven by an external force may be written as:

$$\ddot{x} + \omega_0^2 x - \varepsilon x \dot{x}^2 = F \cos \omega_1 t \quad (5)$$

and

$$\ddot{x} + \omega_0^2 x + b\dot{x} - \varepsilon x \dot{x}^2 = F \cos \omega_1 t \quad (6)$$

where  $\omega_1$  is the driving frequency. The frequency-shift for the undamped, forced oscillator is:

$$\omega_1^2 - \omega_0^2 = -\left( \frac{\varepsilon A^2 \omega_1^2}{4} + \frac{F}{A} \right) \quad (7)$$

which, if  $\omega_1$  is assumed to be close to  $\omega_0$ , reduces to:

$$\frac{\Delta\omega}{\omega} = -\frac{\varepsilon A^2}{8} - \frac{F}{2\omega^2 A} \quad (8)$$

For the damped, forced oscillator the shift is:

$$\omega_1^2 - \omega_0^2 = -\frac{\varepsilon A^2 \omega_1^2}{4} - \sqrt{\left( \frac{F}{A} \right)^2 - b^2 \omega_1^2} \quad (9)$$

or, if  $\omega_1 \approx \omega_0$ :

$$\frac{\Delta\omega}{\omega} = -\frac{\varepsilon A^2}{8} - \sqrt{\left( \frac{F}{2\omega^2 A} \right)^2 - \frac{b^2}{4\omega^2}} \quad (10)$$

Thus, in both instances, the frequency-shift is essentially that of the free, undamped oscillator.

Using a light source of high intensity it may be possible to find the red-shift when the light is scattered in a suitable medium. For a ruby laser, having a wave-length  $\lambda$  6943 Å and an energy flux of  $2 \times 10^{12}$  photons/cm<sup>2</sup>/sec, a frequency shift  $\frac{\Delta\omega}{\omega} \approx 0.5 \times 10^{-4}$  is obtained, if the light is scattered in a plasma with frequency  $\omega_0 = 10^{12}$  and if the experimental value for the Rayleigh scattering cross-section of  $10^{-28}$  is used<sup>4</sup>.

### Transmission of Laser Beams through Various Transparent Rods for Biomedical Applications

THE use of the laser as a surgical tool for the treatment of lesions in tissues other than those of the eye has been reported<sup>1</sup>. Most of these areas treated, however, are those that are readily accessible, making it possible to focus the laser beam directly on the lesion. To apply the laser as an optical knife for surgery, techniques must be developed to direct the laser beam from the laser head to inaccessible areas. This need to change the direction of the laser beam is required not only in the medical field but also in the field of communication.

If the laser beam is needed to impact internal neoplasms and lesions within the body during laser surgery, then it is desirable to use a medium that is safe, flexible, and able to transmit enough energy to be effective without deteriorating. Destruction of portions of pathological lesions has been accomplished by as little as 22 joules/cm<sup>2</sup> or less, but it may be necessary to transmit at least 110 joules/cm<sup>2</sup> or more to other areas, especially those tissues that are not pigmented.

Since the laser is light energy, optical instruments have been used to carry or to reflect this light. These include lenses, mirrors, prisms, and rods both of glass and of plastic. When the laser beam was transmitted through a glass lens of optical quality, approximately 10–12 per cent of its energy was lost. Similarly, when it was transmitted through a quartz prism about 8 per cent of its energy was lost with each reflexion and some of the surface was worn away with each shot. These readings were made with a TRG calorimeter and a Kiethley micro-voltmeter. This energy loss is due to absorption, reflexion and refraction of the light.

Mirrors cannot accept high-energy laser impacts without ruining their reflective coating. We have tried aluminium foil as a reflector with the ruby laser; the surface discoloured rapidly at very low-energy densities. Aluminium foil was used as shielding for the protection of tissues about the impact area. Investigations are under way with gold-plated mirrors for the neodymium and ruby laser.

We have also investigated fibre optics, special types of glass, and plastics. Fibre optics are glass rods with a core glass of one refractive index that is coated or jacketed with another glass of a lower refractive index. This allows light to be directed into one end, and by multiple total internal reflexions it is almost entirely transmitted out of the other end. Bundles of these fibres contain thousands of these rods that are, because of their small size, able to be bent into various angles and curves. Because of their flexibility, they would be an excellent tool for directing the light to internal components of the body. However, flexible bundles of fibre optics (each fibre being about 75 microns in diameter) are not able to take a very high energy without immediate destruction<sup>2</sup>. As little as 17 joules/cm<sup>2</sup> has been enough. Furthermore, these fibre bundles will accept very little energy before they begin to discolour and break down.

The use of non-flexible rods made of crown clad glass is also being considered. Crown clad glass is constructed similarly to that of a fibre optic rod. Thus, when light is directed through one end of a rod of crown clad glass it will be transmitted by internal reflexions to the other end. It has a glass core with a refractive index of 1.523 and a jacket of glass with a refractive index of 1.474. The diameter of the rods we used was 0.5 cm. A straight rod, 20 cm long, was able to transmit 70 per cent of the laser light that was focused on the input surface. This produced an output of 45 joules with an input of 63 joules. A rod 44.5 cm long, with a right-angle bend 30 cm from the end, was able to transmit about 35 per cent, but it shattered, like a small explosion, with an input of 52 joules (Fig. 1). A rod of the same length, bent in six places with gradual angles so that it resembled a semicircle, was able to transmit 50 per cent or as much as 20 joules with an input of 43 joules. Higher inputs were not attempted because of the damage to the right angle. However, experiments are under way to reinforce the areas around the bends with other glass by Dr. Thomas C. MacAvoy, of Corning Glass Co., and it is hoped that this type of rod will stand higher energies. While a rod of crown clad glass may be able to transmit from 50 per cent or even 70 per cent of the input energy, it is rigid and not desirable for lasing internal areas because it cannot be manipulated easily into various positions. However, significant tissue damage was obtained by laser transmission through crown clad glass.

After preliminary examinations on plates of clear epoxy plastics, transmission experiments were conducted on rods of this material. Some of these rods were rigid and others were very flexible. The diameters of the rods used were from 0.5 cm to 0.75 cm, and we used lengths from 15 cm to 70 cm. With the flexible rods we were able to get about 30 per cent transmission of light. These rods were able to accept up to 20 joules input energy, which is about 40 times what the flexible fibre optic bundles could

Fig. 1. Laser impact through right angle bend, crown clad glass

Fig. 2. The black areas of destruction are shown here on three different epoxy rods

Fig. 3. Normal lasing as recorded by an SD-100 detector and a Tektronix 585 A oscilloscope

Fig. 4. Normal lasing as recorded by an SD-100 detector and a Tektronix 585 A oscilloscope after passing through an epoxy rod

withstand. However, at energies above 20 joules input, the epoxy became riddled with black areas of destruction (Fig. 2). When the epoxy was bent at the destroyed areas it broke, but when it was bent (even to 360°) over normal (non-damaged) areas it did not break. These rods did not have a jacketing of epoxy of a lower refractive index, and we have not yet tried coated rods. Thus, we have finally obtained a flexible material that can transmit a percentage of laser light and allow for free manipulation. The amount of energy density that can be accepted and transmitted is not very high, but the possibility of using better optical quality flexible epoxy that may be able to accept much higher energy densities is under investigation.

With the use of oscilloscopes we were also able to demonstrate that the laser light may still retain its coherency after being transmitted through the flexible epoxy bundle (Figs. 3 and 4). Rockwell (personal communication) has proposed the use of a beam-splitter, phototubes, and a dual trace oscilloscope to compare the beams from the same pulse to test coherency. Coherency of the laser beam is an important factor for laser use in

communications and is probably necessary for biomedical applications in order to achieve high-energy densities.

This work was supported by a grant from the John A. Hartford Foundation. Crown clad glass was obtained from Walter P. Siegmund, American Optical Co. Epoxy plates and rods were obtained from Norman S. Strand, Dow Chemical Co.

### Oscillations in the Surface Resistance of Bismuth as a Function of Magnetic Field

KHAIKIN *et al.*<sup>1-3</sup> have observed several types of oscillations in the surface impedance of bismuth single crystals as a function of magnetic field directed parallel to the sample surface. These are cyclotron resonances (CR) of the Azbel-Kaner type<sup>4</sup>, quantum oscillations (QO) which arise because of the separation of allowed electron states into Landau levels, and a third type of oscillation (MO) attributed to the presence of magnetoplasma waves<sup>5,6</sup>. The different kinds of oscillations can readily be distinguished by the ranges of magnetic field over which they occur, and their relative amplitudes. At Khaikin's measurement frequency of 9.5 k Mc/s, C.R. due to electrons and holes occurred at fields below about 700 gauss for all directions of magnetic field with respect to crystal axes. The QO began to appear at fields above about 500 gauss. At fields above a few thousand gauss for certain field directions, large amplitude MO appeared and obliterated the QO.

Khaikin observed the oscillations using his very sensitive frequency-modulation method<sup>7</sup>, and made measurements on crystals of two principal orientations, one having the triad axis normal to the sample surface and the other having the triad and a diad in the plane of the surface. A detailed investigation of the cyclotron resonances was made, but the QO periods could be measured only for magnetic field directions near a diad (within 19° of a diad in the trigonal plane, or within 38° in the triad-diad plane).

We have made a preliminary investigation of a sample having the third principal crystal orientation (triad and a bisectrix in the plane of the sample surface), using a microwave bridge method with magnetic field modulation

and a superheterodyne detection scheme. The sample formed the end of a cylindrical  $H_{11}$  cavity resonating at 9.35 k Mc/s. The output of the bridge, proportional to either  $dR/dH$  or  $dX/dH$  (where  $R + jX$  is the surface impedance of the sample), was plotted against magnet current on an X-Y recorder. Two  $dR/dH$  traces for different magnetic field directions in the sample surface are shown. The scales are the same for both curves, and both were traced out at a rate of about one oscillation per sec. In (a) the CR can be seen at low fields and the QO appear at about 1.5 kgauss. Curve (b) was obtained for a direction of magnetic field nearer to the trigonal axis and is included in order to illustrate the relative magnitude of the MO.

We propose to carry out a detailed investigation of the orientation dependence of the various oscillation periods, and hope thereby to obtain information about the exact form of the energy bands in bismuth. A point of particular interest here is the extent of the departure of the bands from quadraticity<sup>8,9</sup>.

The measurements were made at a temperature of about 1.8° K on bismuth having a resistance ratio somewhat in excess of 100. Liquid helium facilities were made available through the provision of a grant by the Department of Scientific and Industrial Research.

## ENGINEERING

### Stress Patterns in Steel Beams by Autoradiography

PREFERENTIAL dissolution of stressed metal crystals in a polycrystalline sample has been shown by Simnad<sup>1</sup> using <sup>60</sup>Co as a tracer.

In my investigation, preferential dissolution of tensile and compressive stressed areas in a simple cantilever beam experiment was observed.

The 8 × 0.5 × 0.5 in. beams were of mild (1018) steel having the following compositions: Mn 0.88 per cent, C 0.174 per cent, and S 0.036 per cent.

The yield strength was 55 kg/in.<sup>2</sup> and the ultimate tensile strength was 71 kg/in.<sup>2</sup>. The beams were electropolished to remove surface stresses in a mixture of 350 c.c. of 65 per cent perchloric acid and 640 c.c. of glacial acetic acid for 1 min with 20 amp at 25° C.

Two beams were inserted in a grooved steel block (Fig. 1) to a distance of 2 in. and clamped. The bending load was applied by bolting the free ends together so that the ends of both beams deflected toward each other.

Fig. 1. Cantilever beam assembly

Fig. 1. (a) Trace of  $dR/dH$  versus magnet current showing cyclotron resonance oscillations at low fields and quantum oscillations at high fields. (b) Part of a similar trace for a different magnetic field direction showing magnetoplasma oscillations. The range of magnetic field covered was from zero to approximately 5 kgauss

Fig. 2. Autoradiograph of 1018 steel beams previously stressed in a radiotracer solution. Arrows indicate where the beams were bolted together; lighter portions of beams indicate radioactivity

The load was well below the elastic limit of the steel. No permanent deflexion was observed.

The assembly was immersed, bolted end downward, in a solution of 1.05 N  $H_2SO_4$  containing 0.484 mg/ml.  $Fe^{++}$  and 0.0169 mc. of  $^{59}Fe$ . After an immersion time of 1 h at 25° C, the assembly was removed and rinsed until no tracer was found in the rinse water.

Autoradiographs were taken of the beams after releasing the stress load. The autoradiograph (Fig. 2) indicates that the dissolution of a polycrystalline metal beam occurs where either compressive or tensile stress is present. The zero axis (area under the lowest stress) was least attacked by the acid as shown by the light area (denoting radioactivity) on the photograph.

## GEOLOGY

### Probable Life-forms from the Precambrian of the Witwatersrand System (South Africa)

DURING mineralographic work on Witwatersrand gold conglomerates from the Orange Free State goldfield, I encountered several peculiar micro-structures strongly resembling so-called 'mineralized bacteria'<sup>1-4</sup> and, in certain respects, some types of 'organized elements' recently under discussion as possible primitive life-forms in meteorites<sup>5-7</sup>. These structures are preserved in some of the minute detrital pyrite grains of the Elsberg A1 and A3 horizons occurring near the top of the Witwatersrand system, the deposition of which is believed to have been completed about 2,150 million years ago<sup>8</sup>. As the organized elements are indigenous to allogenic components of the rock, they are certainly considerably older.

Morphologically, two types of micro-structures may be discerned. Type 1 forms spherical to sub-spherical granules consisting of a central core-body enveloped in an outer ring suggesting the presence of an external sac (Fig. 1). The granules occur as isolated spots in the pyrite; only in a few cases are individuals seen to touch each other. They measure from 5 to 21  $\mu$  in diameter, the average values lying within the range of 11 to 16  $\mu$ . Internal structures of particular significance could not be distinguished. As a rule, core and outer ring seem to be mostly filled with quartz; occasionally cores displaying pyrite fillings have been observed. It is interesting to note that similar forms have been described by Ramdohr<sup>9</sup> from the Black Reef, that is, considerably higher in the South African stratigraphical column.

Type 2 is represented by spheroidal to elliptical globules surrounded by double-layered walls, each of the constituting layers appearing as a delicate stippled line (Fig. 2). These elements are somewhat smaller than those of type 1: they are between 4  $\mu$  and 16  $\mu$  across, their average ranging from 7 to 11  $\mu$ . In contrast to type 1, these forms very often tend to aggregate in clusters

resembling globose colonies. Neither of the two types described shows indications of spines, protuberances or other appendages.

Structural elements of this size and organization strongly suggest an origin as relics of primitive unicellular life-forms. There is no doubt that early life must have been largely microbial, a circumstance accounting for the fact that the fossil record in the dawn of geological history is deplorably scanty<sup>10</sup>. The pyrite now containing these relict-structures must, at the time of its formation, have provided extremely favourable conditions for the preservation of these bodies. Distinct morphological affinities can be established between the type 1 micro-structures (Fig. 1) and the common species of so-called fossil sulphur bacteria (with the exception of the characteristic 'framboidal' granulation usually present in the latter). Love and Zimmerman<sup>4</sup>, however, described Precambrian forms from the Mt. Isa shale (Australia) which also lacked this framboidal structure. On the other hand, the organized elements of type 2 (Fig. 2) with their apparently perforated walls seem to be somewhat exceptional as compared with forms hitherto known. Allowing for the fact that early micro-organisms must necessarily represent a morphological no man's land, it is preferred to refer to their relics simply as 'organized elements', a designation deliberately avoiding any unwarranted taxonomic specification. This seems the more necessary, as L. G. Love (personal communication), from his investigations of present-day sediments, found reasons to include into the morphological group formerly known as 'fossil bacteria' such taxonomically hetero-

Fig. 1. Organized elements, type 1, from the upper Witwatersrand system (Elsberg A1 reef). (Polished section,  $\times 1,000$ )

Fig. 2. Organized elements, type 2, from the upper Witwatersrand system (Elsberg A3 reef). (Polished section,  $\times 1,000$ )

geneous forms as pollen grains, spores of fungi and algal remains.

Unfortunately, the micro-elements described proved to be too scanty to enable large-scale maceration techniques to be applied, aiming at the isolation of organic material. All considerations as to a biogenic origin of these structures thus being based on purely morphological premises, it must justly be conceded that other possible modes of origin cannot be completely ruled out. Therefore, I would like to advance my conclusions with due reserve, stressing the observed facts rather than their possible (or even probable) explanation.

I thank the Deutsche Forschungsgemeinschaft, Bad Godesberg, for supporting this work, and Prof. P. Ramdohr, Heidelberg, for advice.

## CRYSTALLOGRAPHY

### X-ray Line Broadening Patterns of Halogen Compounds

A SURVEY has recently been carried out into some features of the X-ray line broadening of various halogen compounds, in polycrystalline form, when they have been strained by mechanical working in a ball mill<sup>1</sup>.

Using the method described by Williamson and Hall<sup>2</sup>, strain and crystallite size can be estimated from the integral breadth ( $\beta$ ) by plotting  $\beta^*$  ( $= \frac{\beta \cos \theta}{\lambda}$ ) against

$d^*$  ( $= \frac{2 \sin \theta}{\lambda}$ ), when the slope gives a measure of the strain, and the intercept on the  $\beta^*$  axis gives a value for the reciprocal of the mean crystallite dimension. Integral breadths of the broadened profiles were determined by first separating the  $K\alpha_1$  peak from the  $K\alpha_1\alpha_2$  doublet by graphical means, and then measuring the area of the  $K\alpha_1$  peak above background level and dividing by the maximum peak amplitude. The broadening so obtained shows a general relationship with the order of the reflexion, and by plotting the integral breadth against  $h^2 + k^2 + l^2$  a smooth curve can be drawn to fit the points approximately. This curve would represent the relationship between integral breadth and  $h^2 + k^2 + l^2$  if the material were isotropic, and the deviation pattern of the points from the mean curve thus gives a qualitative measure of the anisotropy of the broadening. The magnitude of this deviation relative to the total broadening, for lithium fluoride and sodium bromide, is shown in Fig. 1.

Eight halogen compounds have been investigated and the deviation patterns of the broadening are shown in Fig. 2. The interesting feature of these patterns is that each is consistent, and characteristic of the particular material, though the relative amplitude of any pattern is dependent on the amount of broadening present.

The patterns show that the broadening of the (400) profile tends to be low relative to the mean, when compared

Fig. 1. Measured integral breadth of worked specimens of lithium fluoride and sodium bromide plotted against  $h^2 + k^2 + l^2$ . The 'scatter' of the points about the smooth curve constitutes the 'deviation pattern'.

Fig. 2. Deviation patterns. Showing the relative deviation from a smooth curve of the measured integral breadth of certain halogen compounds, plotted against  $h^2 + k^2 + l^2$ .

with the (200) profile, where this is present, except in the case of lithium fluoride; the (222) profile, on the other hand, tends to be high relative to the mean when compared with the (111) profile. In terms of  $\beta^*$  versus  $d^*$  analysis this implies that (200)–(400) broadening tends to be associated with lower slope and higher intercept, that is, a less than average strain and smaller than average crystallite size in the [100] direction. The fact that the (222) profiles tend to show higher than average broadening, on the other hand, suggests greater than average strain and higher than average crystallite size.

These results are consistent with the known mechanical properties of these materials. That is, they tend to fracture easily on the (100) plane, hence one would expect a less than average particle size in the [100] direction and less than average value of strain. The converse applies

to the [111] direction, and these properties are confirmed by the deviation patterns already mentioned.

The anomalous pattern of lithium fluoride is outstanding, and this is also consistent with the mechanical properties as indicated by the elastic constants. In common with all cubic metals, except molybdenum, lithium fluoride has its maximum value of Young's modulus in the [111] direction and its minimum value in the [100] direction; whereas, in contrast, all other halides for which the elastic constants are available have their maximum and minimum values of Young's modulus in the [100] and [111] directions respectively. Deviation patterns of this type thus afford a means of estimating qualitatively the elastic constants of a substance when it is only available in a form which precludes direct measurement by other means.

### Direct Observation of Surface Films on Gold

It has generally been assumed that naturally occurring surface films do not exist on gold since it has been classically observed that gold is stable in air. Shishakov<sup>1,2</sup> and Trillat *et al.*<sup>3</sup> have reported thin films of various gold oxides formed on gold surfaces on heating.

The purpose of this work was to investigate films thermally produced in air on gold surfaces using transmission electron microscopy and diffraction in conjunction with a recently developed technique to remove the films from the metal.

Surfaces of pure ( $\sim 99.97$  per cent) gold were produced by two methods. The first was to grow slowly a crystal horizontally from the melt in a graphite boat after the surface of the liquid had been scraped clean with a quartz scraper. When solidification was complete, the crystal was cooled to room temperature. The atmosphere was a mixture of argon and air. The crystals produced by this method were either single crystals or very large-grained polycrystals. The second method was to mechanically polish a coarse-grain polycrystal with alumina abrasive until as smooth a surface as possible was produced. The crystal was then heated in air to  $1,030^\circ\text{C}$  for 15 min and cooled. Both methods served to remove any previously existing surface films.

The technique used for isolating the surface films for electron microscopy has been described by Doherty and Davis<sup>4</sup>. On cooling, pits bounded by low-index crystallographic planes nucleated and grew under the film in the metal by the condensation of lattice vacancies. In all cases, it was observed optically that these pits had formed. At room temperature, a layer of cellulose nitrate was applied to the surface and stripped off, removing those areas of the surface film over vacancy pits. After shadowing with platinum at an angle of incidence of  $18^\circ$ , a thin film of carbon was deposited on to the cellulose nitrate. The cellulose nitrate was then dissolved away, and the carbon film containing the fragments of surface film was viewed in normal transmission in the electron microscope with a 50-kV beam. In all cases, observation was confined to a single grain.

Fig. 1 shows the appearance of typical fragments of surface film removed from a crystal solidified from the melt. The fragments of surface film from the mechanically polished crystals are similar. Their various geometrical shapes correspond to the morphologies expected of vacancy pits. Careful inspection of many electron micrographs showed that they do not cast a shadow, indicating that their thickness is not more than about

Fig. 1. Fragments of surface film (lighter than background due to photographic reversal) removed from a crystal solidified from the melt. Scale represents  $1\mu$ .

$25\text{ \AA}$ , the smallest height resolvable by this shadowing technique. Fig. 2 is a typical transmission electron diffraction pattern produced by an individual fragment of surface film from a mechanically polished crystal, and is similar to those produced in the case of the crystals solidified from the melt.

For the crystals solidified from the melt, the diffraction pattern produced by the fragments of surface film could be identified as that of a basal-oriented hexagonal lattice structure. On one orientation of the gold substrate which was close to the (221) plane, every fragment of surface film produced a diffraction pattern. The pattern showed that the fragments were not only basal-oriented, but were identically-oriented azimuthally, indicating that the

Fig. 2. Electron diffraction pattern produced by surface film removed from a mechanically polished crystal. The rings are produced by the platinum shadowing material.

surface film was a single crystal. An  $a_0$  lattice parameter of  $3.48 \text{ \AA} \pm 0.9$  per cent was calculated. This value was checked with the known hexagonal oxides, nitrides, carbides, cyanides and binary intermetallic compounds of those impurity metals detected by spectrographic analysis of the gold. It is in closest agreement with the  $a_0$  value of  $3.395 \text{ \AA}$  ( $c_0 = 5.080 \text{ \AA}$ ) obtained for bulk AuCN from X-ray measurements performed by the National Bureau of Standards<sup>5</sup>. On all other substrate orientations examined, only a small fraction of the fragments of surface film produced detectable diffraction spots. The patterns observed showed that these fragments were all basal-oriented but randomly oriented azimuthally, indicating that, with the exception of the one epitaxial case, all the surface films examined from crystals grown from the melt were polycrystalline. The  $a_0$  parameter was calculated to be  $3.48 \text{ \AA} \pm 1.1$  per cent, which is the same value as that obtained for the epitaxial film.

For all the mechanically polished crystals, only a small fraction of the fragments of surface film produced detectable diffraction spots. All the patterns could be identified as that of a basal-oriented hexagonal structure and were randomly oriented azimuthally. We thus conclude that these films were polycrystalline. From these patterns, an  $a_0$  lattice parameter of  $5.30 \text{ \AA} \pm 0.8$  per cent was calculated which is in closest agreement with the  $a_0$  value of  $5.28 \text{ \AA}$  obtained by Shishakov<sup>2</sup> using *in situ* electron diffraction, for thin films of  $\text{Au}_2\text{O}_3$  (hexagonal,  $c_0 = 6.75 \text{ \AA}$ ) formed on gold by heating to  $500^\circ \text{C}$  in oxygen. In addition, the pattern produced by one fragment could be interpreted as a hexagonal structure rotated  $70^\circ$  from the basal orientation about the  $a_1$  axis so that the beam lay in the  $[0221]$  direction. From this pattern, an  $a_0$  parameter of  $5.34 \pm 1.8$  per cent and a  $c_0$  parameter of  $6.56 \pm 1.6$  per cent were calculated.

Since, on all observed substrate orientations except (221), only a small fraction of the fragments of the surface films produced detectable diffraction spots, one cannot conclude whether or not there is any preferred orientation in these polycrystalline films. Presumably, due to the small mass of the fragments, only those fragments having low-index orientations produced spots of sufficient intensity to be detected.

For gold, the temperature range or ranges of vacancy pit nucleation during cooling are not known, and, since the range(s) could be quite broad, no quantitative conclusions can be drawn concerning the temperature or temperatures at which the surface films formed except that they formed somewhere between a temperature near the melting point of gold ( $1,063^\circ \text{C}$ ) and room temperature.

## CHEMISTRY

### Rate Constant for the Reaction of $\text{O}^-$ with Oxygen

We have measured the rate constant for the reaction  $\text{O}^- + \text{O}_2 \rightarrow \text{O}_3^-$  by irradiating a solution of aerated  $10^{-1} \text{ N}$  potassium hydroxide with a short pulse of fast electrons and observing directly the growth of the transient species  $\text{O}_3^-$  which has an absorption maximum at  $4300 \text{ \AA}$  (refs. 1 and 2).

Fig. 1. *a*, Oscillogram showing the duration of the  $0.2\text{-}\mu\text{sec}$  electron pulse as indicated by the Čerenkov radiation. Abscissa scale,  $0.5 \mu\text{sec/cm}$ . *b*, Growth of absorption at  $4300 \text{ \AA}$  due to the species  $\text{O}_3^-$ . Ordinate scale,  $1.67$  per cent absorption/cm. Abscissa scale,  $2 \mu\text{sec/cm}$ . Solution:  $10^{-1} \text{ N}$  potassium hydroxide saturated with air and with nitrous oxide.

The apparatus and conditions of irradiation were generally similar to those already described<sup>1,3</sup>, but the electron pulse in this case had a duration of only  $0.2 \mu\text{sec}$  (see Fig. 1*a*) and delivered a dose of about  $1 \text{ krad}$  to the solution. To increase the  $\text{O}^-$  concentration the solution was saturated with nitrous oxide, which reacts with the electron to give  $\text{O}^-$ . To reduce the speed of the reaction of  $\text{O}^-$  with oxygen, we saturated the solution with air instead of pure oxygen.

Fig. 1 shows two successive growth curves for the species  $\text{O}_3^-$ , obtained by means of a monochromator, photomultiplier and oscillograph set to record at  $4300 \text{ \AA} \pm 150 \text{ \AA}$ . The light source used was a  $450\text{-W}$  xenon lamp. The input network of the oscilloscope had an integrating time constant of  $0.3 \mu\text{sec}$ .

The duration of the electron pulse is clearly indicated in the  $\text{O}_3^-$  growth curve by the initial negative peak due to Čerenkov emission. Each of these curves gives a linear first-order plot taking the origin at the point where the trace crosses the axis. The mean slope, based on several experiments, is  $0.76 \times 10^6 (\text{sec})^{-1}$ . The correction for the oscilloscope time constant leads in this case, paradoxically, to a slight reduction in the slope, and we estimate the first-order rate to be  $0.66 \times 10^6 (\text{sec})^{-1}$ . Since the oxygen concentration was  $250 \mu\text{M}$  the second-order rate constant,  $k$ , is  $2.6 \times 10^9 \text{ M}^{-1} \text{ sec}^{-1}$ .

We have not as yet found a complete absorption spectrum for  $\text{O}^-$  itself, but there is some evidence that it absorbs at wave-lengths near  $2600 \text{ \AA}$ . Fig. 2 shows the decay with time of the absorption at  $2600 \text{ \AA} \pm 100 \text{ \AA}$ .

Fig. 2. Oscillogram showing the absorption at  $2600 \text{ \AA}$  following a  $2\text{-}\mu\text{sec}$  pulse to a  $10^{-1} \text{ N}$  solution of potassium hydroxide initially anoxic and containing  $8 \text{ mM}$  nitrous oxide. Ordinate scale,  $3.5$  per cent per cm. Abscissa scale,  $100 \mu\text{sec/cm}$ .

when an initially de-aerated solution of  $10^{-1}$  N potassium hydroxide containing about 8 mM nitrous oxide is irradiated by a single 2- $\mu$ sec pulse. The oscillogram shows two components, one of which has vanished in about 100  $\mu$ sec, while the other lasts for a relatively long time. The fast component is, we believe, due to  $O_2^-$ , and it lasts much longer than the  $O_3^-$  build-up in Fig. 1 because there is only a trace of oxygen in the solution, this having been formed by radiolysis during the pulse. The peak vanishes after two or three pulses have been given to an initially de-aerated solution. The long-lived component is due to  $O_2^-$ . It declines a little by reacting with the trace of  $O_3^-$  formed, and then remains practically constant for many msec.

We thank Mr. M. C. Crowley-Milling for the design of the fast-pulse circuitry, and Mr. Dieter Rebmann for help with its construction.

### Polonium in Cigarettes—Spectroscopic Analysis

ALPHA-RADIOACTIVITY in cigarettes has recently been measured by two groups. Turner and Radley<sup>1</sup> suggested that  $^{210}\text{Pb}$  and  $^{210}\text{Po}$  are not present in the raw tobacco at levels of activity of the same order as  $^{226}\text{Ra}$ , and concluded that the additional  $\alpha$ -activity taken into the lungs from the radium content in cigarettes is less than 1 per cent of the atmospheric radon inhaled by both smokers and non-smokers. Radford and Hunt<sup>2</sup>, however, maintained that polonium is more dangerous because of its volatility above 500° C. They identified the  $^{210}\text{Po}$  content of cigarettes by observing  $\alpha$ -activity of 138 days half-life, and estimated the radiation dose to bronchial epithelium from  $^{210}\text{Po}$  inhaled in cigarette smoke to be at least seven times that from background sources, and in localized areas possibly up to 200 times.

The investigation recorded here was undertaken in order to: (1) identify spectroscopically and measure the amount of  $^{210}\text{Po}$  as well as other polonium isotopes in cigarettes; (2) present a fast and reliable detection system capable of determining accurately minute quantities of  $^{210}\text{Po}$  (of the order of  $10^{-2}$   $\mu\text{c}$ .) as well as of mixtures of  $\alpha$ -active isotopes.

Polonium was extracted from whole cigarettes using a wet ashing procedure<sup>3</sup>. The polonium samples deposited on silver foils were then placed at a distance of a few mm from a 2-cm<sup>2</sup> solid-state detector, which was coupled into a low-noise, charge-sensitive preamplifier and a multi-channel analyser<sup>3</sup>. The effective solid angle was  $3.8 \pm 10$  per cent steradians. The overall energy spread of a monoenergetic  $\alpha$ -group was about 50 keV. Alphas from known sources of  $^{241}\text{Am}$ ,  $^{238}\text{U}$ ,  $^{212}\text{Po}$ , and  $^{212}\text{Bi}$  were used for energy calibration. This procedure can determine energies of unknown  $\alpha$ -groups to  $\pm 15$  keV. Two samples, each containing polonium from two cigarettes, were measured. The two samples were prepared from cigarettes of the same brand but from different cartons and were both found to contain  $0.45 \pm 0.10$   $\mu\text{c}$ . per cigarette, in agreement with Radford and Hunt<sup>2</sup>. The quoted uncertainty is mainly due to the uncertainty in solid angle and in plating efficiency. Background was 0.1–0.2 counts/h and was less than 1 per cent of the sample activity. A polonium  $\alpha$ -spectrum accumulated for 6 h

Fig. 1. Polonium  $\alpha$ -spectrum accumulated for 6 h from a two-cigarette sample

from a two-cigarette sample is shown in Fig. 1. The location of the peak corresponds to an energy of  $5.310 \pm 0.015$  MeV, in excellent agreement with the value of 5.305 MeV for  $^{210}\text{Po}$ .

Although all polonium isotopes are  $\alpha$ -active, no  $\alpha$ -activity due to any other polonium isotopes was observed, with an upper limit of 1 per cent. This result is not surprising since all polonium isotopes which belong to the radioactive series have too short half-lives to be observed in our experiment, and there is no apparent process which can yield other polonium isotopes in large amount. There is an agreement to within 15 per cent between the activity of our two samples and between our samples and those of Radford and Hunt<sup>2</sup>. Though this agreement may be fortuitous, it at least suggests that the amount of polonium per regular size American cigarette (about  $2 \times 10^5$  atoms) does not fluctuate extensively, and may reflect the homogenizing procedure used in the production of cigarettes.

We have also performed a preliminary measurement of the polonium collected on a glass-wool filter when whole cigarettes were smoked in a stream of oxygen inside a heated flask. This preliminary measurement indicates that most of the polonium follows the smoke, in agreement with the findings of Radford and Hunt<sup>2</sup>. If we assume that about 10 per cent of the polonium content of the cigarette eventually decays in the lung, the amount of  $^{210}\text{Po}$  activity at equilibrium for a person smoking 50 cigarettes a day can reach a level of 400  $\mu\text{c}$ . Unfortunately, biological data for the efficiency of the lung for the uptake and retention of polonium in cigarette smoke are not available to test this assumption<sup>4</sup>. Such a value, although not alarming, can be a cause for concern if concentrated in small areas of the respiratory system<sup>2</sup>. We believe that the questions of polonium retention and localization are very important and should be fully investigated. We also have not yet investigated the question of equilibrium in the cigarette between  $^{210}\text{Po}$  with a half-life of 138 days and one of its parents  $^{210}\text{Pb}$  with a half-life of 22 years. This question is significant if ageing is to be considered as a possible remedy. The dependence of  $^{210}\text{Po}$  and  $^{210}\text{Pb}$  concentrations on factors such as rain<sup>5</sup>,

soil, irrigation, fertilizers, etc., should also be investigated. It is also conceivable that proper glass filters might retain a significant part of the inhaled polonium, as indicated by Radford and Hunt<sup>2</sup> and by our preliminary measurement.

Other polonium-absorbing materials such as silver or nickel should also be considered. In any event, we strongly believe that  $\alpha$ -spectroscopy, which utilizes apparatus similar to that described here, can be a powerful tool in the investigation of all these questions. It could also help in the investigation of radioactivity of polluted air from factory smoke and automobile fumes. Such an experimental system is practically free from background. It permits determination and identification of minute quantities of  $\alpha$ -active isotopes. Counting efficiency of up to 100 per cent, and with no appreciable loss in energy resolution, can be achieved with the use of 2 solid-state detectors connected in parallel in a 4 $\pi$  arrangement, and sources plated on very thin foils. In short, a spectroscopic system is unambiguous and fast, and is therefore preferable to systems which utilize analysis by half-life.

### Synthesis of Substituted Phenyl- $\beta$ -D-xylopyranosides

INVESTIGATIONS into the specificity of a  $\beta$ -xylosidase required the synthesis of a number of substituted phenyl- $\beta$ -D-xylosides. A very important method is the Helferich reaction in which the appropriate phenol and the fully acetylated monosaccharide are heated in the presence of an acidic catalyst. To favour the formation of xyloside-acetates with the  $\beta$ -anomeric configuration, *p*-toluenesulphonic acid and  $\beta$ -tetra-*O*-acetyl-xylose were used<sup>1</sup>.

The corresponding xylosides were prepared by catalytic deacetylation of the acetates.

Tetra-*O*-acetyl- $\beta$ -D-xylose was prepared according to Vogel<sup>2</sup> and twice crystallized from ethanol: m.p. 127°–128°.

The xylosetetraacetate (31.8 g; 0.1 mol.) and the appropriate phenol (0.4 mol.) were fused together and the molten mixture treated with a solution of *p*-toluenesulphonic acid (0.6 g) in a mixture of acetic acid and acetic anhydride (95:5; 50 ml.). The mixture was heated under reduced pressure at 100° for 1 h. After cooling, the resulting syrup was dissolved in chloroform (200 ml.), thoroughly washed with ice-cold N sodium hydroxide and water, dried ( $\text{Na}_2\text{SO}_4$ ) and evaporated *in vacuo*. The resulting syrup was then crystallized from the appropriate solvent to constant m.p. and optical rotation.

The *ortho*-substituted phenol, *o*-chlorophenol, failed to react in the presence of *p*-toluenesulphonic acid even at higher temperature. Jermyn<sup>3</sup> likewise reports inability to obtain *o*-chlorophenyl-tri-*O*-acetyl- $\beta$ -D-glucoside by this method. However, we succeeded in obtaining the *o*-chloroderivative by a modified Michael synthesis<sup>4</sup>. To a solution of *o*-chlorophenol (8.95 g; 0.07 mol.) in acetone (192 ml.), potassium hydroxide (3.36 g) in methanol (50 ml.) and acetobromoxylose (20 g; 0.059 mol.) were added. After 5 h at room temperature the mixture was

### Analysis of the Absorption Spectrum of Solutions of Uranyl Compounds

THE absorption spectra of solutions of uranyl compounds between 20,000 and 28,000  $\text{cm}^{-1}$  show some features which have, at least to our knowledge, not been stressed in the literature.

Indeed, if  $\Delta\nu$  is plotted against decreasing values of  $\nu$  the results shown in Fig. 1 are obtained;  $\Delta\nu$  being the

Fig. 1. Vibronic intervals as a function of the wave-numbers of the vibronic maxima in the absorption spectra of solutions of uranyl compounds. The figures next to the points refer to different spectra

difference in wave-number values for two successive absorption maxima expressed in  $\text{cm}^{-1}$  and  $\nu$  being the wave-number at which these maxima appear, also in  $\text{cm}^{-1}$ . The  $\Delta\nu$  values are plotted against the lower of the two wave-number values  $\nu$ , from which they are obtained.

Fig. 1 was established from data of eleven different spectra for uranyl perchlorate, nitrate and phosphate dissolved at various concentrations in water, alcohol and acetone. Vibronic analysis data from Jezowska-Trzebiatowska and others<sup>1,9</sup> are not reported on the figure, although they actually do fit rather well on it.

At some wave-numbers in the absorption spectra of uranyl the vibronic maxima are rather poorly defined. This is certainly so, along with the co-excitation of others than the uranyl symmetric vibration with electronic excitation, at the origin of the scatter of the points on Fig. 1. However, Fig. 1 does show an important feature.

One can distinguish a regularity in the values of  $\Delta\nu$  for different values of  $\nu$ . Roughly one can say that  $\Delta\nu$  equals approximately  $800 \text{ cm}^{-1}$  between  $27,500$  and  $25,500 \text{ cm}^{-1}$ ,  $650 \text{ cm}^{-1}$  between  $25,500$  and  $22,500 \text{ cm}^{-1}$ , and some  $750 \text{ cm}^{-1}$  between  $22,000$  and  $20,000 \text{ cm}^{-1}$ . Around  $25,500$  and  $22,500 \text{ cm}^{-1}$  the  $\Delta\nu$  values are intermediate between  $650$  and  $800 \text{ cm}^{-1}$ .

These three spectral regions, which one can distinguish according to  $\Delta\nu$  values, coincide strikingly with the regions which have been proposed by several authors for three electronic transitions in the  $20,000$ – $28,000 \text{ cm}^{-1}$  absorption spectrum of uranyl<sup>2-5</sup>. Therefore, any decrease in  $\Delta\nu$  for increasing  $\nu$  values, which could be considered as significant of a convergence of bands within each one of the three regions, could be used to calculate potential energy curves for the three electronically excited states  $^3\Pi_{2u}$ ,  $^3\Pi_{1u}$  and  $^3\Pi_{0u}$  (ref. 4) of the uranyl ion.

In fact, the  $\Delta\nu$  values within each region are, for the reasons just mentioned, too irregular and there are too few of them to consider them as belonging to a convergent series of bands. Nevertheless, we did so and calculated in a classical way<sup>6</sup> potential energy curves for the excited states already mentioned here. We used the Badger relation as given by Jones<sup>7</sup> for uranyl in its ground-state to calculate equilibrium internuclear distances U–O for each of the three excited states. The energy of the  $0'-0''$  bands for each of the three excited states are estimated by extrapolation from the positions of the  $1'-0''$  and  $2'-0''$  bands in the three electronic transitions suggested in an earlier communication<sup>5</sup>.

The potential energy curves given on Fig. 2 were calculated from the spectrum of uranyl perchlorate in water (the most favourable case: points 1 on Fig. 1). The potential energy values of Fig. 2 were calculated in  $\text{cm}^{-1}$  for the ground-state energy equal to  $0 \text{ cm}^{-1}$ .

Although from a theoretical point of view these curves may be far too inaccurate, their comparison with experimental results does give them some significance. Indeed, the calculated value of  $28,690 \text{ cm}^{-1}$  for the asymptote of the potential energy at infinite atom separation in the  $^3\Pi_{0u}$  state roughly corresponds to the appearance of a continuum at about  $28,200 \text{ cm}^{-1}$  in most uranyl absorption spectra. The corresponding calculated value of  $32,250 \text{ cm}^{-1}$  for the  $^3\Pi_{1u}$  state strongly recalls a feature of the uranyl absorption spectrum reported by Pringsheim<sup>8</sup>. He distinguishes band structure superposed on a continuum up to about  $32,573 \text{ cm}^{-1}$  in the absorption spectrum of  $1/20 \text{ M}$  uranyl sulphate in water.

Fig. 2. Potential energy curves for the lowest excited states of the uranyl ion in solution

Application of the Franck-Condon principle to the proposed relative positions of the potential energy curves appears, at first sight, to agree with the observed difference in intensity distribution between the absorption and phosphorescence spectra of uranyl compounds. (Phosphorescence of uranyl is used here instead of fluorescence, as suggested by McGlynn and Smith<sup>4</sup>). In absorption the  $2'-0''$  band of the  ${}^3\Pi_{1u} \leftarrow {}^1\Sigma_g^+$  (ref. 5) transition appears to be the most intense one, while in emission it is the  $1'-0''$  band of the transition  ${}^3\Pi_{0u} \rightarrow {}^1\Sigma_g^+$  which appears to be the most intense band.

The irregularities in the band structure of the uranyl absorption spectrum have been considered as indicative of "distinct negative vibrational anharmonicity"<sup>9</sup> of uranyl in its lowest excited state. The present analysis of this absorption spectrum yields an explanation for these irregularities which is in good agreement with other evidence<sup>4,5</sup> for the triplet character of the lowest excited state of uranyl.

This analysis is now being applied to the absorption spectra of a great number of uranyl compounds in order to check its general validity.

We thank Prof. A. van Tiggelen for encouraging this work and the Fonds de la Recherche Scientifique Fondamentale et Collective for financial support.

### Some New Co-ordination Compounds of Copper(II) Chloride

WE wish to report the preparation of a series of 1:1  $\text{CuCl}_2$  ligand compounds which appear to have polymer type structures. The ligands used in this investigation were 1,2-diazine (pyridazine); 1,3-diazine (pyrimidine); 1,4-diazine (pyrazine); 1,2,4-triazole; 1,10-phenanthroline and 2,2'-bipyridine.

Interest in this area of investigation arose from our belief that a comparison of the copper(II) complexes formed with bidentate ligands in which the two nitrogen donors have different relative locations in the ligand molecule might provide insights into the structures of these complexes. Moreover, the crystal structures of the 1,2,4-triazole- $\text{CuCl}_2$  complex reported by Jarvis<sup>1</sup> led us to expect that the preparation of a variety of  $\text{CuCl}_2$ -ligand polymers should be possible.

All compounds herein reported were prepared by the addition of excess solid  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$  to the ligand dissolved in water. Chemical analysis (for example, the  $\text{CuCl}_2$ -1,2-diazine complex yielded the following analysis: calc.: Cu, 29.61; Cl, 33.05; found: Cu, 29.65; Cl, 33.14.  $\text{CuCl}_2$ -1,4-diazine. Calc.: Cu, 29.61; Cl, 33.05; found: Cu, 29.21; Cl, 32.74) indicated a chlorine to copper ratio of 2:1 and a  $\text{CuCl}_2$  to ligand ratio of 1:1. All the compounds were green, and the mull spectra of these compounds showed maxima near  $1.4 \times 10^4 \text{ cm}^{-1}$ , and all

exhibited strong absorption in the ultra-violet. The minimum in absorption between the two observed bands in every case was near  $1.8 \times 10^4 \text{ cm}^{-1}$ .

Comparison of the observed mull spectra with mull and solution spectra of numerous other copper(II) compounds leads to the conclusion that the bands centring near  $1.4 \times 10^4 \text{ cm}^{-1}$  are due to  $d-d$  transitions (ligand field bands) and that the intense ultra-violet bands arise from ligand absorption and/or charge transfer processes. Since the ligand field at the cupric ion is provided almost entirely by the nearest neighbour environment, the marked similarity in band position and shape suggests that the copper(II) ion has nearly the same local environment in all these complexes.

The model which appears to be most consistent with these facts is one which places cupric ions in chains and in which the ligands are utilized as cupric ion-cupric ion links. The low water solubility of the compounds supports the chain-type polymer structure. In terms of this model, a ligand with adjacent nitrogens as in 1,2,4-triazole and 1,2-diazine connects copper(II) ions within a chain as shown schematically in Fig. 1. Ligands with non-adjacent nitrogens within a single ring such as 1,3-diazine and 1,4-diazine connect different chains as shown schematically in Fig. 2. (The stereochemistry of the nitrogens in the phenanthroline molecule suggests that this copper chloride complex would be of the type shown in Fig. 1. However, the possibility of rotation about the carbon-carbon bond in 2,2'-bipyridine allows that it could act as an intra- or inter-chain link.) A model of this type has also been proposed for  $\text{NiCl}_2$ -1,4-diazine complex by Lever, Lewis and Nyholm<sup>2</sup>. In each of the proposed structures, then, the copper(II) ion has a co-ordination number of six, lies at or near the centre of four in-plane chloride ions, and has one ligand nitrogen above and another below the plane.

Fig. 1. Schematic representation of intra-chain bonding in copper chloride-ligand polymers

Fig. 2. Schematic representation of inter-chain bonding in copper chloride-ligand polymers

Other possible structures have also been considered. For example, a model involving copper in tetrahedral co-ordination was considered unlikely on the grounds that a  $1.4 \times 10^4 \text{ cm}^{-1}$  band (with no evidence for additional  $d-d$  bands between  $1.4 \times 10^4 \text{ cm}^{-1}$  and  $4.5 \times 10^3 \text{ cm}^{-1}$ ) is not at all consistent with  $d-d$  bands of copper compounds known to be tetrahedral<sup>3</sup>. A four co-ordinate model ('square planar') was also considered unlikely because of the different steric requirements of the ligands which would be expected to produce differences in the optical spectra. No such differences have been observed.

We believe that the information at present available supports the six-fold co-ordination of the copper(II) ions; however, only a single-crystal X-ray examination can elucidate the exact details of these structures. Attempts are now in progress to grow single crystals of these compounds and the results of magnetic and optical measurements will be reported later.

## BIOCHEMISTRY

### Glucose Metabolism and $\alpha$ -Keto-acids in Rat Brain and Liver *in vivo*

GLUCOSE is the major substrate for the brain<sup>1,2</sup>, which utilizes a very high proportion of the bodily glucose requirement<sup>3</sup>. Whittam<sup>4</sup> has calculated that about 40 per cent of the energy produced from glucose metabolism in the brain is required for ion transport mechanisms important in maintaining the physiological function of the tissue. Over the past few years a number of workers<sup>5-8</sup> have demonstrated the high rate of incorporation of carbon-14 from glucose into brain amino-acids, particularly glutamic acid. It has been suggested<sup>6</sup> that the amino-acids have a special role as intermediates in the brain; that their formation and oxidation constitute a major pathway of glucose metabolism in the brain. However, the characteristically high concentration of free glutamate in the brain, in contrast to other tissues, renders methods of investigations which are based on the labelling of the amino-acid pools, rather than specific activity measurements on individual amino-acids isolated from the tissues, rather inconclusive. As has been suggested<sup>9</sup>, such results could be due to quantitative differences in glycolysis and transamination reactions between the brain and the liver.

This communication reports the main results of an investigation into the incorporation of carbon-14 from glucose into the  $\alpha$ -keto-acids in rat brain and liver. The previous emphasis has been on glutamate which has been shown to be involved in potassium transport<sup>2,10</sup>, so this work has been carried out *in vivo* since potassium transport, and possibly therefore glutamic acid metabolism, is suboptimal in cerebral cortex slices<sup>11</sup>. These experiments form part of a more extensive investigation which will be published in detail shortly.

Glucose-U-<sup>14</sup>C (15  $\mu\text{C}$  in 0.5 ml. saline, obtained from the Radiochemical Centre, Amersham) was injected subcutaneously into 100 g male rats of the Wistar albino Glaxo strain (obtained through the courtesy of Dr. C. M. Mauritzen, Department of Biochemistry, University of Melbourne). At various times (2-40 min) after injection, the rats were killed by decapitation, the blood was

immediately collected in heparinized beakers and deproteinized by pipetting a measured volume (usually 1 ml. into cold 6 per cent perchloric acid. Also immediately after death, the tissues were rapidly excised and frozen in liquid nitrogen. The time from decapitation to complete freezing of the tissues was usually effected within 1 min and never exceeded 1.5 min. The tissues were weighed, dropped while still frozen into cold 6 per cent perchloric acid (6 ml./g) and dispersed in a 'Teflon'-pestle homogenizer (A. H. Thomas Co., Philadelphia). After centrifugation the protein residues were washed by resuspension in cold perchloric acid.

Two-thirds of the combined supernate and washings was brought to room temperature (20-25°) and reacted with one-tenth the volume of 2 : 4-dinitrophenylhydrazine (0.2 per cent in 2 M HCl) for 30 min. (The remainder of the acid extract was neutralized with KOH at 0° and the precipitated KClO<sub>4</sub> was removed by centrifugation. This neutral extract was stored frozen for subsequent isolation of amino-acids and sugar intermediates.) The keto-acid dinitrophenylhydrazones were extracted into ethyl acetate (10 + 5 ml.) at 0° in the absence of light by buzzing on a Vortex shaker. All extractions were performed at 0° in the dark with a Vortex shaker since it was found that a brown contaminant, similar to that reported by Neish<sup>12</sup>, appeared on subsequent chromatograms if these precautions were not observed, or if mixing was by aeration. The ethyl acetate extract was washed once with water (5 ml.) and the dinitrophenylhydrazones were purified by extraction into 10 per cent Na<sub>2</sub>CO<sub>3</sub> (2 ml.) and washed with ethyl acetate (5 ml.). After dropwise acidification with chilled concentrated HCl, the dinitrophenylhydrazones were re-extracted into ethyl acetate and washed with water according to the usual procedure<sup>13</sup>. The extracts were dried over anhydrous Na<sub>2</sub>SO<sub>4</sub> and the solvent was removed to *in vacuo* at < 10°. The residue was dissolved in the minimum volume of ethyl acetate, transferred to a micro-test-tube and concentrated to about 20  $\mu\text{l}$ . in a gentle stream of dry nitrogen. The total extract from each tissue sample was applied in 2  $\mu\text{l}$ . aliquots to thin-layer plates of cellulose and chromatographed at 3° in the dark in butan-1-ol : ethanol : 0.5 M ammonia (7 : 1 : 2 by vol.) as previously described<sup>14</sup>. The plates were dried in an air-stream, after which the discrete spots were clearly visible. Only rarely was a spot of oxaloacetic acid dinitrophenylhydrazone discernible, and then in too small amounts (about 0.2-0.5  $\mu\text{g}$ ) to allow for accurate quantitation.

Each spot was scraped off the plate into a micro-test-tube and the derivative was eluted into cold 10 per cent Na<sub>2</sub>CO<sub>3</sub> (0.5 ml.) by 'buzzing' and rapid centrifugation in a Servall SST. The extracts could then be estimated directly at 380 m $\mu$  (ref. 15) in 0.4 ml. micro-cuvettes of the 'Spectrochem' (Hilger and Watts). However, since radioactivity measurements were to be performed, it seemed advantageous to estimate the keto acids in the same sample as that to be counted. The Na<sub>2</sub>CO<sub>3</sub> extracts were acidified (HCl) at 0° by buzzing in the presence of ethyl acetate (0.6 ml.); the ethyl acetate extract was dried over anhydrous Na<sub>2</sub>SO<sub>4</sub> and estimated directly at 360 m $\mu$ . The molar extinctions of the dinitrophenylhydrazones (pyruvate : 19,800; oxaloacetate : 25,600;  $\alpha$ -oxoglutarate : 23,500) were very similar to those obtained<sup>15</sup> in Na<sub>2</sub>CO<sub>3</sub> at 380 m $\mu$ , so no sensitivity was lost. The recovery of synthetic keto-acid derivatives through the whole process ranged from 96 to 102 per cent. In all the tissue extracts, in which storage-time under acid conditions was kept to a minimum (the extractions and estimations were all performed within the same day under controlled conditions of light and temperature), no separation of *syn-anti* isomers<sup>14</sup> was observed.

Radioactivity measurements were made using a Packard 'Tricarb' model 314 EX liquid scintillation counter at -10° in the scintillator described by Patrick<sup>16</sup> except that it was found necessary to include dioxane (10

Fig. 1. Uptake of carbon-14 from circulating blood glucose-U-<sup>14</sup>C into keto-acids isolated from rat tissues. Each point is the average of 4-6 experiments. Brain keto-acids: pyruvate (●), α-oxoglutarate (○); liver keto-acids: pyruvate (■), α-oxoglutarate (□)

per cent by volume). The absolute efficiency was 70 per cent and no quench correction was found to be necessary for dinitrophenylhydrazones up to 15 μg in 10 ml. scintillator. Glucose, after isolation by paper chromatography<sup>17</sup>, was estimated with glucose oxidase<sup>18</sup> and counted in the Packard using the scintillator described by Bruno and Christian<sup>19</sup>. In contrast to their report, water did quench—the efficiencies observed for standard <sup>14</sup>C-toluene were: in 10 ml. scintillator, 65 per cent; with 0.5 ml. H<sub>2</sub>O, 62.5 per cent; with 1.0 ml. H<sub>2</sub>O, 60 per cent. Samples of 0.5 ml. were counted and the 62.5 per cent efficiency was extrapolated to 70 per cent for comparison with the keto-acids.

The incorporation of the carbon-14 from glucose into the keto-acids is shown in Fig. 1, where the specific activities (c.p.m./μmole) are plotted against the time (min) after injection of <sup>14</sup>C-glucose. It can be seen that whereas there is no difference in the carbon-14 content of the individual keto-acids from the same tissue, the brain keto-acids are labelled more rapidly and attain a higher proportion of the carbon-14 from the circulating glucose than do the keto-acids in the liver—in a pattern similar to that reported for the amino-acids<sup>5,6</sup>. Whereas some variation was observed in the specific activities of intermediates isolated from identically-treated individual animals, this variation was observed also in the labelling of the circulating glucose, and the relative specific activities (c.p.m./μmole keto-acid versus c.p.m./μmole blood glucose) were quite consistent, especially in the longer time experiments as shown in Table 1. At 30 min

Table 1. INCORPORATION OF CARBON-14 INTO KETO-ACIDS ISOLATED FROM THE BRAIN AND LIVER OF RATS AFTER INJECTION WITH GLUCOSE-U-<sup>14</sup>C

Time (min) after injection	R.S.A. Brain keto-acids		R.S.A. Liver keto-acids	
	Pyruvate	α-Oxoglutarate	Pyruvate	α-Oxoglutarate
2	4(4) ± 0.4			
5	10(6) ± 0.3	12(4) ± 1.2	3(4) ± 0.4	2(4) ± 0.2
10	16(6) ± 1.1	13(4) ± 1.4	4.5(4) ± 0.9	3(4) ± 0.1
20	13(2)			
30	14(6) ± 0.5	14(6) ± 0.4	4(6) ± 0.03	3.5(6) ± 0.02
			(P < 0.001)	
40	12(2)		4(2)	

Male rats were injected subcutaneously with 15 μC glucose-U-<sup>14</sup>C, and the keto-acids extracted and isolated as described in the text. The results are expressed as relative specific activities (R.S.A.).

R.S.A. =  $\frac{\text{counts/min/μmole free keto-acid}}{\text{counts/min/μmole blood glucose}} \times 100$  (number of animals) ± S.E.

after injection, the relative specific activity of the brain pyruvate or α-oxoglutarate is 3-4 times higher than that of the liver acids, the difference being highly significant ( $P < 0.001$ ).

These results suggest that the rapid labelling of the amino-acid pool in brain is a reflexion of a rapid general utilization of glucose, since the brain keto-acids are also more highly labelled. They support the view<sup>3</sup> that more active glycolysis and rapid isotopic exchange by transamination between α-keto-acids and amino-acids can adequately account for the rapid incorporation of carbon-14 from glucose into glutamate.

I thank Prof. J. Bornstein for his advice.

## Growth Hormone Action on Rat Liver RNA Polymerase

HYPOPHYSECTOMY of the adult rat results in a loss of weight and protein content of the liver and other tissues<sup>1</sup>. These effects can be reversed by treatment of the rat with growth hormone. This control by growth hormone of protein biosynthesis is reflected in alterations in the ability of ribosomal preparations of liver and other tissues to incorporate amino-acids into protein *in vitro*<sup>2</sup>. The hormonal control of protein synthesis can be at least partially explained in terms of hormonal control of the rate of synthesis of messenger and other RNA<sup>3,4</sup>.

One possible point at which growth hormone could exert its effect on RNA synthesis is through the activity of the RNA polymerase enzyme<sup>5</sup> (*E.C.2.7.7.6*). The effect of growth hormone on the activity of this enzyme was, therefore, investigated.

Rats were killed by decapitation and the liver rapidly removed into ice-cold 0.5 M sucrose containing 3 mM magnesium chloride, cut up with scissors, and washed free of blood. The liver was homogenized in the same medium, filtered through gauze and a crude nuclear pellet prepared by centrifugation at 600g for 5 min. The crude pellet was suspended once in the sucrose-magnesium chloride medium and recentrifuged at 600g. The pellet was suspended in 2.2 M sucrose<sup>6</sup> and centrifuged at 22,000 r.p.m. for 1 h in the SW 25 rotor of the Spinco model L centrifuge. The pellet produced by this procedure was free of red blood cells and contained very few whole liver cells on observation by light microscopy. These purified

nuclei were suspended in 0.05 M *tris* buffer, pH 8. The protein/DNA ratio of the nuclei was about 4.5/1 and there were no significant differences in this ratio between the nuclei prepared from differently treated rats. DNA was determined by the method of Burton<sup>7</sup>, and protein by the method of Lowry *et al.*<sup>8</sup>, using thymus DNA and bovine serum albumin as standards.

The RNA polymerase activity of the nuclei was assayed by a slight modification of the method of Goldberg<sup>9</sup>. The reaction was started by adding nuclei to 0.5 ml. of a mixture containing 100 mM *tris* buffer pH 8.2, 5.0 mM mercaptoethanol, 20 mM sodium fluoride, 3 mM manganese chloride, 60 mM potassium chloride and 0.5 mM each of ATP, GTP, CTP and UTP. One of these nucleoside triphosphates was labelled with <sup>14</sup>C or <sup>3</sup>H. After addition of the nuclei the tubes were incubated at 37° for varying periods and the reaction stopped by the addition of 1 ml. of saturated sodium pyrophosphate solution. 1 mg of bovine serum albumin carrier was added followed by 5 ml. of cold 0.5 M perchloric acid to precipitate the protein and nucleic acids. The precipitate was washed twice with cold perchloric acid, twice with ethanol and twice with ethanol: ether (1:1). The dried precipitate was either dissolved in formic acid and plated on to weighed metal planchets and the radioactivity assayed in a gas-flow counter, or the dried material was dissolved in hyamine and counted in a scintillation counter. The results, expressed as  $\mu$ M of labelled nucleoside triphosphate incorporated per mg of DNA added have been corrected for zero time values. The latter were less than ten c.p.m.

Table 1. CHARACTERISTICS OF RNA POLYMERASE ASSAYED IN RAT LIVER NUCLEI

	$\mu$ M <sup>14</sup> C-ATP incorporated/mg DNA 20 min incubation	60 min incubation
Complete medium	488	450
Omit GTP	40	—
Omit UTP	45	—
Omit GTP	100	—
Add 100% DNAase	55	—
Add 50% actinomycin	33	—
Add 0.05 ml. satd. ammonium sulphate	2,680	6,400

The results, depicted in Table 1, show that incorporation is dependent on the addition of all four of the nucleoside triphosphates and on the presence of native DNA. Incorporation is greatly stimulated by a medium of high ionic strength as was previously noted<sup>9</sup> for the system from HeLa cells. Maximal stimulation on raising the ionic strength of the medium was obtained by the addition of 0.05 ml. of saturated ammonium sulphate (saturated at 4° C). It was noted that incorporation is complete in 15 min if ammonium sulphate is not added, but in the presence of high concentration of ammonium sulphate incorporation continued for at least 90 min.

The effect of growth hormone on the activity of the RNA polymerase measured in this system is shown in Table 2. It can be seen that hypophysectomy of the rat results in decreased activity of the RNA polymerase and that the injection of 1 mg of human growth hormone into the rat 12 h before death increased the enzyme activity both in hypophysectomized rats and in normal rats. However, the stimulating effect of growth hormone was only seen in the absence of high concentrations of ammon-

ium sulphate; raising the ionic strength of the assay medium abolished the growth hormone effect. It should be mentioned that addition of growth hormone *in vitro* in the presence or absence of ammonium sulphate has had no significant effect on the labelling of the RNA by the nuclear preparations.

Gorski<sup>10</sup> found that oestrogen treatment of rats resulted in an increase of RNA polymerase activity of uterus but that the presence of high concentrations of ammonium sulphate abolished the oestrogen effect.

Widnell and Tata<sup>11</sup> have shown that thyroid hormone treatment of rats resulted in an increase in liver RNA polymerase activity after about 16 h. They also showed<sup>12</sup> that growth hormone stimulated RNA polymerase activity and that the effects of the two hormones were additive. Their investigations<sup>13</sup> led them to conclude that the action of ammonium sulphate could be explained by unmasking of a second DNA-dependent RNA polymerase activity. An alternative explanation<sup>9</sup>, which our own results favour, is that raising the ionic strength increases the incorporation of nucleoside triphosphates into RNA because of some activation of the DNA-RNA polymerase enzyme complex. If this were the case it would be possible to argue that the action of growth hormone *in vivo* is similar to that of high concentrations of ammonium sulphate *in vitro*; that is to say, that growth hormone acts by facilitating the formation of the DNA-enzyme complex, or perhaps the movement of the enzyme relative to the DNA template. This possible mechanism of growth hormone action and other possibilities are being investigated.

### Blood Content of Rat Liver Homogenates

EVEN though the presence of blood in tissue homogenates is quite evident, its implication in the interpretation of results is generally ignored. In work on rat liver tissue, this attitude results from an under-estimation of the blood content by earlier investigators<sup>1-4</sup>. In order to gauge to what extent blood 'contamination' must be taken into account, a very accurate determination of blood content of homogenates is essential. A simple and accurate method, free from the errors inherent in procedures used so far, is described here. It consists in (1) complete extraction of haemoglobin from liver with sodium deoxycholate (DOC) followed by a specific spectrophotometric determination of haemoglobin; (2) evaluation of blood content in homogenates by comparing it with the blood from the same animal.

Table 2. GROWTH HORMONE TREATMENT OF RATS ON LIVER NUCLEAR RNA POLYMERASE ACTIVITY

	$\mu$ M <sup>14</sup> C-GTP incorporated/mg DNA No A.S.*	+0.05 ml. satd. A.S.
Normal rats	326	1,920
Normal rats given 1 mg human growth hormones 12 h previously	700	1,910
Hypophysectomized rats	218	1,880
Hypophysectomized rats treated with growth hormone	392	1,800

\* A.S., ammonium sulphate.

Determinations were made on 2 groups of rats (Wistar sub-strain *WAG*, fasted, adult males). In group *A*, livers from rats anaesthetized with ether were used; in group *B*, livers were removed after decapitating and bleeding the rat. After ligaturing the median lobe, the portal vein was severed and the liver was quickly perfused with one of several isotonic solutions through the inferior vena cava. The liver was removed and a 2.5 per cent homogenate was prepared by homogenizing separately the perfused and non-perfused (median) lobes, in physiological salt solution containing 0.5 per cent (w/v) DOC. The median lobe represents the whole tissue (*W*) the blood volume of which is to be evaluated, and the perfused lobes (*P*) are used as the control tissue. Whole blood samples were obtained, in *A*, by cardiac puncture after the median lobe had been ligatured and, in *B*, by collecting after decapitation. The homogenates were centrifuged at  $150,000g_{av}$  during 30 min. The film formed on the surface was discarded and the clear supernatant was collected. Using the extract from *P* as blank, the optical density of the extract from *W* was measured at 542 m $\mu$ . Simultaneously the optical density determinations of the blood samples, after 200-fold dilution with 0.5 per cent DOC, were also made.

The values obtained for blood content are given in Table 1: an average value of  $21.09 \pm 2.38$  (*S.D.*) as g blood/100 g tissue for non-exsanguinated and one of  $8.60 \pm 1.67$  (*S.D.*) for exsanguinated rats were obtained. These results call for three remarks: (1) results achieved by Gibson *et al.*<sup>5</sup> permit us to correlate the haemoglobin concentration of blood in the hepatic vessels with that of the total circulating blood, since, according to these authors, both haematocrit values are the same, which, however, is not the case with all organs; (2) variations in the values in *B* are greater than in *A*; this could evidently be attributed to the unequal extent of bleeding in the different animals after decapitation; (3) these values are much greater than the different values reported: 3.7–5.2 per cent<sup>4</sup> for non-exsanguinated and 2.3–6 per cent<sup>1</sup>, 1.5–5.2 per cent<sup>2</sup>, 1.86 per cent<sup>3</sup> for exsanguinated rats.

Table 1. BLOOD CONTENT IN RAT LIVER HOMOGENATES

	Exp. No.	Optical density at 542 m $\mu$		Blood content of homogenate	
		0.5% blood in 0.5% DOC	2.5% homogenate in 0.5% DOC	In ml./100 g liver *	In g/100 g liver †
Nonexsanguinated animals	1	0.522	0.459	17.52	18.48
	2	0.589	0.511	17.36	18.30
	3	0.486	0.526	21.64	22.81
	4	0.535	0.506	22.38	23.49
	5	0.576	0.632	21.92	23.11
	6	0.469	0.452	19.27	20.30
Exsanguinated animals	11	0.594	0.227	7.65	8.07
	12	0.580	0.216	7.45	7.86
	13	0.590	0.217	7.36	7.76
	14	0.559	0.287	10.26	11.83
	15	0.550	0.264	9.60	10.12
	16	0.558	0.157	5.62	5.94
	17	0.485	0.182	7.51	7.91
	18	0.538	0.264	9.82	10.35

\* Values calculated by the following formula:

$$\frac{\text{optical density of 2.5\% homogenate} \times 100}{\text{optical density of 0.5\% blood} \times 5}$$

† Specific gravity of rat blood, 1.054.

The main sources of possible error have been totally eliminated in our experiments. That there is no adsorption and that the extraction of haemoglobin from DOC-treated tissue is quantitative is shown, for each animal, by the experiments where known and increasing amounts of blood were added to homogenates from *P*. In Fig. 1, the optical densities at 542 m $\mu$  of the DOC extracts were plotted against the concentration of blood in the homogenates. The resulting straight line intersects the origin, thereby indicating a total absence of haemoglobin adsorption on the cell components. Further, the average optical density of the extract from *P* containing 0.5 per cent blood has been found, for 14 individual experiments, to be

Fig. 1. Relative concentration of added blood recovered from the perfused tissue homogenates. Optical density of supernatants obtained from tissue treated with 0.5 per cent DOC, measured using similar supernatants from perfused tissue as blanks

identical with that of DOC extract of 0.5 per cent blood alone ( $0.545 \pm 0.042$ ). (Adsorption could explain low values obtained by Holzer<sup>1</sup> and Pragay's<sup>2</sup> techniques.) Error due to turbidity is avoided by preparing homogenates in saline solution, thereby permitting sedimentation of residual cell components. Interference caused by the coloured substances of the liver (bile, pigments, cytochromes, flavins, etc. . . .) is overcome by using supernatants from perfused liver as the blank; the absorption spectra 2 and 3 in Fig. 2 of the DOC-treated blood and the homogenate are, indeed, identical.

Regarding the method of estimation of haemoglobin, convincing evidence could be obtained to suggest that it accounts for the total haemoglobin content of the blood: (1) Although the quantity of reduced haemoglobin is not appreciable in our blood preparations, as could be expected, all determinations were made at 542 m $\mu$ , a wave-length at which the extinction coefficients of haemoglobin and oxyhaemoglobin are equal<sup>6</sup> and, therefore, effects due to any possible variation in the oxyhaemoglobin/haemoglobin ratios are abolished. This should also make it possible to have a rough estimate by directly comparing the absorption of the supernatants from tissue homogenates to the average extinction coefficient of rat blood:

$$\left( E_{1 \text{ cm}, 542}^{0.5\%} = 0.545 \right)$$

(2) The absolute similarity in the spectrum of blood treated and not treated with DOC shows the absence of denaturation of oxyhaemoglobin by DOC.

This method of haemoglobin determination could be applied to all tissues that could be perfused. From the results obtained in these investigations it could be established that the amount of blood present in liver homogenates is not negligible, in whatever manner the animal may be killed. It follows that allowances have to be made for blood contents as a rule or, better still, that investigations have to be carried out on perfused livers. In the results expressed per unit weight of tissue or per unit weight of nitrogen, errors are only appreciable in the case of substances the activity or concentration of which is different in blood and in tissue. This permits us to assume that the values are inaccurate for the determination of concentrations of glucose-6-phosphate, 3-phosphoglycerate, adenosine di- and tri-phosphate malate, etc.<sup>7</sup>,

Fig. 2. Absorption curves for blood and rat liver supernatants. ··· 0.1 per cent blood; --- 0.5 per cent blood in 0.5 per cent DOC; — 2.5 per cent tissue homogenate treated with 0.5 per cent DOC

or the enzyme content in adenosine deaminase, ribonuclease, cholinesterase, acid phosphatase, aldolase, etc.<sup>8</sup>, in liver tissues. In so far as values are expressed in terms of DNA, blood content in DNA not being appreciable, the error is greater and this holds for all substances which are to be found in blood.

Finally, it should be emphasized that contamination by blood particularly affects analyses of both nuclei and cell sap isolated by differential centrifugation. Corpuscles, indeed, only contaminate the former, whereas plasma and what haemoglobin has been freed contaminate the latter. This introduces errors to the extent of 20 per cent in the nitrogen determination, for example, on the liver cell sap obtained from exsanguinated rats, and more than 40 per cent on the cell sap obtained from non-exsanguinated rats.

These artefacts occur in all organs, such as kidney, lung, spleen, where there is an intense blood supply.

### Effect of Curare on the Incorporation of <sup>32</sup>P-Orthophosphate in Rat Gastrocnemius Muscle

SOME biochemical changes in mitochondria isolated from pigeon breast muscle after section of motor nerve have been reported<sup>1</sup>, and the turnover of high-energy phosphate was markedly slowed after nerve section (Cessi *et al.*<sup>2</sup>). These reports suggest that some regressive biochemical changes of the main energy-producing cell structures are brought about by denervation.

Since the discovery of the effect of curare in inducing muscle paralysis, much work has been done on its structure and pharmacological actions<sup>3</sup>. It is known to antagonize acetylcholine, which is believed to transmit nerve impulses from a motor nerve to skeletal muscle. A protein which binds curare, acetylcholine and related compounds has been isolated from electric organs<sup>4</sup> and was identified as the receptor protein. Curare is said to combine with this receptor protein, on which acetylcholine normally acts to initiate the propagation of nerve impulse; it therefore blocks the motor terminals, causing the failure of contraction after stimulation. In this sense, curarization might be regarded as a sort of chemical denervation. The aim of these experiments was to observe whether some metabolic changes, especially in the turnover of high-energy phosphates, could be induced by blocking the neuromuscular transmission with *d*-tubocurarine.

Albino rats (weighing approximately 300 g) were injected with *d*-tubocurarine (400 μg/kg) after inserting a metal cannula into the trachea for artificial respiration by a respirator under pentobarbital sodium anaesthesia (80 mg/kg). To check the degree of curarization, an electrode was connected with the sciatic nerve and electrical stimulus was given by a stimulator. Muscle reactivity was recorded on a kymograph from the time when curare was injected. When the kymograph showed the reappearance of muscle contraction, another dose of curare was injected, maintaining the fully curarized state continuously.

Two hours after the curare injection, <sup>32</sup>P-orthophosphate (1 mc./kg) was injected intraperitoneally. Two hours after the radioactive phosphorus injection, gastrocnemius muscle was rapidly removed from the animal and an extract was made with 0.6 M perchloric acid according to the method described by Buffa *et al.*<sup>5</sup>. The extract was neutralized with potassium hydroxide and, after separation of potassium perchlorate, introduced into a column of 'Amberlite IRA-400', formate form, 400 mesh, 1 × 18 cm. The elution was carried out with the formic acid-formate system described by Hurlbert *et al.*<sup>6</sup>, with slight modifications. The radioactivity and the extinction at 260 mμ of the effluent were measured continuously and recorded. 3-ml. fractions were collected and the phosphorylated compounds identified by the ultra-violet spectrum were measured on a Beckman DU spectrophotometer. The specific activities of labile phosphates were determined by measuring the concentration of phosphorus after hydrolysis (18 min, 2 N sulphuric acid, 100° C) with the method of Martin and Doty<sup>7</sup> and the radioactivity of the same butanolic extract was measured with a well-type Geiger-Müller counter. The control group was treated in the same way, except for the curare injection.

The incorporation of <sup>32</sup>P-orthophosphate into the organophosphate was considerably inhibited after 4 h of continuous curarization (Table 1). The inhibitory effect of curare might be due to an inhibition of phosphorylation mechanism, or to an interference with phosphate entry, or transport to the muscle cell. In physically denervated muscle, Cessi *et al.*<sup>2</sup> reported lower specific activity of the phosphate involved in energy transformation and suggested that this may simply reflect a decreased demand for ATP in the paralysed muscle. It is also quite possible to suppose that the metabolism of muscle in completely relaxed state by curare could be diminished and the

Table 1. EFFECT OF CURARE ON THE RATE OF  $^{32}\text{P}$ -ORTHOPHOSPHATE INCORPORATION. VALUES ARE PRESENTED AS THE SPECIFIC ACTIVITY OF TISSUE INORGANIC PHOSPHORUS BEING TAKEN AS 100, AND AS THE MEAN OF THREE EXPERIMENTS

	Specific activities relative to inorganic P of tissue

Table 2. CONCENTRATION OF ADENINE NUCLEOTIDES IN CONTROL AND CURARIZED GROUP

	Micro moles of adenine nucleotides per g of fresh tissue	
	Control	Curarized
AMP	0.54 $\pm$ 0.14	0.58 $\pm$ 0.14
ADP	1.02 $\pm$ 0.33	0.83 $\pm$ 0.34
ATP	4.42 $\pm$ 0.72	3.44 $\pm$ 0.84

requirement of energy would also be decreased as an example of self-regulation or feedback in a biological system. The little differences in the concentration of adenine phosphates seem to support this view. However, the marked difference in the ratio of specific activity of blood phosphate to inorganic phosphorus of tissue in curarized muscle suggests that another factor is responsible for the phosphate entry or transport. As the detailed mechanism of the efficient cellular organization for fast resynthesis and recycling of the nucleotide is still obscure, it remains to be established whether some possible changes in the membrane permeability by curare-receptor complexes have some effect on this slowing down of high energy phosphates.

## Two-dimensional Separation of Nucleic Acid Bases on Cellulose Layers

THIN-LAYER chromatography on cellulose layers has been shown to be an effective method for separation and quantitative determination of nucleic acid bases, nucleosides and nucleotides<sup>1-5</sup> which has considerable advantages over paper chromatography. Keck and Hagen<sup>5</sup> recently reported a one-dimensional thin-layer chromatographic separation of the four major bases of RNA and DNA. The present communication describes a two-dimensional procedure which in this laboratory has proved useful for separating more complex mixtures of nucleic acid bases.

**Preparation of cellulose layers.** 20 g cellulose powder MN 300 (Macherey and Nagel, Düren, Germany) are suspended in 120–130 ml. distilled water, homogenized in a Waring blender for 15–20 sec, and coated on degreased glass plates in the usual way, using a Stahl-type applicator<sup>6</sup> adjusted to a slit width of 0.5 mm (Desaga, Heidelberg, Germany). The plates are allowed to dry at room temperature for 10–15 h.

**Chromatographic procedure.** Chromatography is carried out in closed rectangular jars filled with solvent to a height of about 0.8 cm. It is not necessary to saturate the tank atmosphere with solvent vapours. Solvents used are: (1) methanol/concentrated hydrochloric acid/water (70:20:10, v/v), for the first dimension; (2) *n*-butanol/

Fig. 1. Two-dimensional separation of nucleic acid bases on a 0.5 mm-cellulose layer. A solution of 0.5–1.5  $\mu\text{g}$  of each compound was applied in ten 1  $\mu\text{l}$ . portions to the start spot. Solvents: see text. First dimension from right to left, second dimension from bottom to top. Development distances: 10 cm in either direction. The black areas of the photograph are parts of the layer which were removed before the second development. Total development time: about 150 min. T=thymine; U=uracil; C=cytosine; HMC=5-hydroxy-methyl cytosine; A=adenine; H=hypoxanthine; G=guanine. (Photography in short-wave ultra-violet light)

methanol/water/concentrated ammonium hydroxide (60:20:20, v/v), for the second dimension. The plate is dried between the two developments for 3–5 min in a current of cold air, then for 5 min in a current of hot air (60°–70° C) in order to remove hydrochloric acid as completely as possible.

Fig. 1 shows a separation of a mixture of bases. The main advantages of this method are its speed, sensitivity and sharpness of resolution.

This work was supported by grants-in-aid from the U.S. Atomic Energy Commission, the U.S. Public Health Service, the National Science Foundation, and the Burroughs Wellcome Fund.

## Carbonyl Chloride Cycle in Uraemia

THE role of carbonyl chloride in the production of uraemic coma has been emphasized in previous publications<sup>1,2</sup>. It has been further demonstrated that urea reacting with ammonium chloride *in vivo* produces carbonyl chloride with the liberation of ammonia. In view of the enormous number of cases of uraemia already handled by the author it appears that a plausible suggestion with regard to the biochemical steps involved in the production of carbonyl chloride and associated compounds is called for.

Urea is formed in the liver in the cycle described by Krebs<sup>3</sup>, involving the mediation of arginase. In the production of uraemic coma the conversion of urea to carbonyl chloride is involved<sup>1</sup>. The intermediate steps may be outlined as follows:

In the first stage of the reaction one molecule of urea reacts with two molecules of free chlorine ( $\text{Cl}^{\cdot}$ ) to produce carbonyl chloride and  $2\text{NH}_2$ . Further reaction with two molecules of free sodium ( $\text{Na}^+$ ) results in two molecules of sodium amide in addition to the carbonyl chloride already existing. Finally, reaction with two molecules of water yields free ammonia and two molecules of sodium

hydroxide. The free  $\text{NH}_3$  thus formed enters again into Krebs urea cycle.

The entire reaction of the  $\text{COCl}_2$  cycle as suggested above is diagrammatically represented in Fig. 1.

The mode of reaction suggested seems to be consistent with the known facts, and it probably represents the true state of affairs in the production of  $\text{COCl}_2$ .

### Photoreceptive Pigments for Anthocyanin Synthesis in Apple Skin

LIGHT is required for anthocyanin synthesis in many plant tissues. Appreciable synthesis of idaein (cyanidin 3-galactoside) in the apple skin,  $1.0 \times 10^{-5}$  moles/cm<sup>2</sup> of skin, requires 7 joules/cm<sup>2</sup> incident energy at the action maximum near 650 m $\mu$  and about three times as much energy in the region of the subsidiary maximum between 430 and 480 m $\mu$  (ref. 1). This high-energy photoreaction, which will later be referred to as the HER, usually must be followed by a photoreaction establishing the photomorphogenic pigment, phytochrome, in the far-red absorbing form ( $P_{fr}$ ) which requires about  $3 \times 10^{-3}$  J/cm<sup>2</sup> for half saturation at the action maximum near 655 m $\mu$  (ref. 2). A number of photomorphogenic responses of plants including control of flowering and etiolation suppression, but not seed germination, involve both a high-energy reaction and the action of  $P_{fr}$  (ref. 3). The photoreceptive pigment has not previously been identified for the HER in apple skin or other objects and  $P_{fr}$  has not been shown to be necessary for idaein synthesis.

Our findings indicate that the photoreceptor for the HER in apple skin is the photosynthetic system. The maximum near 650 m $\mu$  in the action spectrum for the anthocyanin formation<sup>1</sup> corresponds to the red absorption maximum of chlorophyll *b*. A broad subsidiary maximum between 420 and 470 m $\mu$  is in the region of a broad maximum effective for excitation of system 2 for photosynthesis. The apple skin contains chlorophyll in the hypodermal cells in which anthocyanin synthesis takes place. Low-temperature ( $-196^\circ\text{C}$ ) spectroscopy of the apple skin revealed the presence of chlorophyll-*b*, chlorophyll-*a* (abs. max. 670 m $\mu$ ), chlorophyll-*a* (abs. max. 680 m $\mu$ ), and  $P_{700}$  in ratios approximately those of green plants. Photosynthesis is weakly displayed. Apple skin

scraped free of underlying tissue, under an irradiation of 3.5 mW/cm<sup>2</sup> (the order of  $1 \times 10^{-6}$  Einsteins/cm<sup>2</sup> min) in the region of 400–680 m $\mu$  (illumination of 1,000 ft. candles with a white fluorescent source), gave an oxygen evolution of  $4 \times 10^{-8}$  moles/cm<sup>2</sup> min, which was about twice the oxygen consumption in darkness. The rate of photosynthesis relative to respiration, however, varied between samples of skin and some did not reach compensation under such conditions.

Chlorophyll fluorescence from scraped apple skin was measured to determine if both photosynthetic pigment systems 1 and 2 (ref. 4) were functional. One manifestation of the dual pigment system relating directly to the photosynthetic enhancement phenomenon in green plants is the change in fluorescent yield of chlorophyll-*a* which accompanies supplementary radiation in the red and far-red regions<sup>4,5</sup>. Measurements on apple skin showed a 30 per cent greater fluorescent yield following supplementary red radiation as compared with far-red radiation. These measurements indicated that the dual pigments of photosynthesis and the associated electron transport chain were functioning. The light-induced changes in fluorescence were inhibited by more than 75 per cent by  $2 \times 10^{-6}$  M DCMU (3-(3,4-dichlorophenyl)-1,1-dimethyl urea). This reagent is known to abolish the fluorescent yield changes by blocking the photosynthetic electron transport chain<sup>4,5</sup>.

The rate of anthocyanin synthesis in Arkansas apple skin floating on 10 per cent sucrose solution, after an induction period, varies linearly with intensity above 0.3 mW/cm<sup>2</sup> irradiation in the region of 600–680 m $\mu$ . A concentration of  $1.0 \times 10^{-6}$  M DCMU inhibited the rate of synthesis in the linear region by 50 per cent, which was also the degree of inhibition of oxygen evolution. The proportional change in photosynthesis and anthocyanin formation was closely similar for several DCMU concentrations leading to inhibitions between 0 and 100 per cent (Fig. 1).

The rate of anthocyanin synthesis in the skin of mature apples held for three months in storage was enhanced about two-fold by sucrose. It is evident that sucrose, either stored or supplied, and other substrates which were partially endogenous, rather than direct photosynthetically-derived compounds, supply the carbon substrate for the HER. The impression previously held was that anthocyanin synthesis in many green plants is inhibited rather than enhanced by chlorophyll<sup>6</sup>. The observed enhancement of anthocyanin synthesis as chlorophyll

Fig. 1. Inhibition of photosynthesis (oxygen evolution) and anthocyanin synthesis in apple skin by 3-(3,4-dichlorophenyl)-1,1-dimethyl urea (DCMU).

decreases probably arises, however, from increased sugar supply. This is strikingly evident in the red colorations of many leaves in autumn and of young growth in the spring when the days are cool.

Apple skin produces ethanol and acetaldehyde in darkness<sup>7</sup>. This production is immediately terminated by adequate radiation with alternative production of idaein. The metabolic reaction in which the HER enters is accordingly considered to be in the region of pyruvate utilization. The chlorophyll system is apparently contributing directly to this reaction on irradiation. The manner of the contribution, however, is unknown and might consist in the supply of an oxidant, a reductant, an energy or phosphate source (adenosine triphosphate) or, less likely, in direct energy transfer. The control might also be effected by a side reaction of the electron transport chain. In the apple skin the action spectrum for anthocyanin synthesis resembles pigment system 2 in having a pronounced contribution by chlorophyll-b, but in other tissues the HER action maxima agree more closely with pigment system 1. Such variability might be expected, but at this juncture it remains to be examined.

Presence of phytochrome in the P<sub>fr</sub> form, which is produced with maximum effectiveness in the region of 600–680 mμ, is necessary for display of the HER in several carefully examined responses<sup>8</sup>. Failure of its detection in others apparently arises from nuances of the P<sub>fr</sub> action. In anthocyanin synthesis in sorghum cultivar 'Wheatland', P<sub>fr</sub> action follows the HER by an average interval of about 4 h, which is the time required for substrates produced by the HER to undergo dark reactions before undergoing enzymatic change by P<sub>fr</sub> (ref. 8). The low effectiveness of anthocyanin synthesis in apple skin dictates long times of irradiation at high intensities for appreciable synthesis. In the apple skin the radiation most effective for HER is also most effective for establishing P<sub>fr</sub>, and periods of irradiation are long compared with 4 h. Both facts tend to obscure P<sub>fr</sub> action. The action, however, was successfully demonstrated. Arkansas apple skins floating on 10 per cent sucrose irradiated for 16 h (3.5 mW/cm<sup>2</sup> in the 400–680 mμ region, 1,000 ft. candles white fluorescent) to overcome an induction period, were placed in darkness for 24 h before an additional 24-h irradiation period (3.5 mW/cm<sup>2</sup>). The skins were then returned to darkness for 24 h at 20° C for completion of idaein synthesis. They contained  $1.70 \times 10^{-8}$  idaein/cm<sup>2</sup>. In other lots of skin, subjected to brief far-red irradiation at the start of the first dark period to convert the phytochrome to the red-absorbing form, the idaein content was reduced to  $1.42 \times 10^{-8}$  M/cm<sup>2</sup>. A second short irradiation of another lot with red light to re-establish P<sub>fr</sub> gave  $1.75 \times 10^{-8}$  M idaein/cm<sup>2</sup>. Maintenance of P<sub>fr</sub> throughout the 24-h period by a continuous red irradiance of 2 μW/cm<sup>2</sup> enhanced the idaein content to  $2.65 \times 10^{-8}$  M/cm<sup>2</sup>. These enhancements are evidence of P<sub>fr</sub> action on the substrate supplied by the HER.

## PHYSIOLOGY

### Adrenal Medullary Hormones and Sensitization of Mice to Histamine by the Histamine-sensitizing Factor of *Bordetella pertussis*

*Bordetella pertussis* cells, or extracts from them, increase the sensitivity of mice to histamine, serotonin, toxic materials, various stresses and anaphylaxis. This profound effect, observed to different degrees in various strains of mice, is almost entirely duplicated by adrenalectomy<sup>1,2</sup>. For this reason, it has long been suspected that the mode of action of *B. pertussis* involves the adrenal glands either directly or indirectly<sup>1,3</sup>. *B. pertussis*-treated mice can be protected from histamine death by injection of cortisone or hydrocortisone, but treatment with epinephrine 30 min before histamine challenge was not effective. Consequently, it has been assumed that the steroid hormones were the significant factor in the histamine sensitization phenomenon<sup>1,2</sup>. In adrenalectomized mice, it has been demonstrated that both epinephrine and steroids protect mice from histamine death<sup>3</sup>. It should be stressed that no evidence has been uncovered to show that the histamine-sensitizing factor (HSF) extracted from *B. pertussis* cells directly affects the adrenal glands. No histological abnormalities or changes in the amount of steroids produced have been observed<sup>2</sup>. To account for this lack of direct effect on the adrenal gland, it was proposed that the *B. pertussis* effect might be due to an indirect effect at a site removed from the adrenal glands, such as blocking the site of action of an important adrenal hormone.

Fishel *et al.*<sup>4,5</sup> have recently postulated a mechanism involving mainly the adrenal medullary hormones. They have found that substances such as dichloroisoproterenol (DCI) or nethalide, which block the 'beta-adrenergic' receptors, produce effects which mimic the increased susceptibility of *B. pertussis*-treated mice to histamine and serotonin. Their hypothesis is that *B. pertussis* interferes with the beta-adrenergic receptors, thus producing an imbalance between the reactivity of beta and alpha receptors to epinephrine, and they assume that this increased reactivity of the alpha receptors to epinephrine accounts for the greater sensitivity to histamine and serotonin. This hypothesis then assigns an important part to the medullary hormones. However, this view does not explain why adrenalectomized mice show an increased sensitivity to histamine, and suggests that exogenous epinephrine should not protect HSF-treated mice from histamine shock.

This preliminary note substantiates previous work on adrenalectomized mice<sup>6</sup> and rats<sup>6</sup> concerning the involvement of the medullary hormones in the sensitization to histamine and indicates that HSF may block the effect or the site of action of epinephrine and possibly other catechol amines.

Adrenalectomized mice react in many ways like HSF-treated mice. It was recently found that removal of the adrenal medulla alone produced increased histamine sensitivity. A representative experiment is given in Table 1. Demedullated animals became highly sensitive to the injection of histamine. This effect was not due to a degeneration of the whole adrenal since healthy cortex tissue was found on histological examination at 33 days post-operation. The medulla, however, at the time the sections were taken, showed little, if any chromaffin tissue in the mice that died of histamine shock. Medullary tissue was present in the 'demedullated' mice that survived the shock. It was found that as little as 1.25 to 2.50 μg of *l*-epinephrine given intravenously protected demedullated or adrenalectomized mice from an intraperitoneal challenge with 0.5 mg of histamine base (Table 2).

The prime requirement for protecting mice from histamine challenge by epinephrine is that it must be given

\* CFIV 6-week-old mice were given either 5 or 10  $\mu$ g HSF i.v. 24 h before challenge with 0.5 mg histamine base given i.p. Treatment with *l*-epinephrine was given i.v. one-half min after challenge. Control mice received saline instead of *l*-epinephrine.

† D/T: deaths/total number of animals.

shortly after the histamine challenge. Although it is known that large doses of relatively insoluble steroids (4 mg of cortisone or hydrocortisone) given intraperitoneally 24 h before histamine shock protect mice, smaller and more nearly physiological doses apparently do not protect them. In the present work, 50  $\mu$ g/mouse of corticosterone failed to protect adrenalectomized mice from histamine shock, when the steroid was given from 24 h to 30 min before challenge. Moreover, no demonstrable synergistic or additive effect between the steroid and *l*-epinephrine was shown.

These results indicate that, if adrenal hormones are indeed involved in the activity of HSF, the process might mainly be through interference with the action of medullary hormones, as suggested by Fishel *et al.*<sup>4,5</sup>. If the mode of action of *B. pertussis* is that of blocking adrenergic receptors, it should be more difficult to protect *B. pertussis* mice with catechol amines such as *l*-epinephrine. Preliminary results indicate that this is actually the case (Table 3). If the mechanism of HSF can be assumed to be a blocking of receptor sites in the effector organs, this blockage must be quite irreversible since it lasts for a long period of time (3 weeks or more) and cannot easily be overcome by an excess of catechol amines.

As indicated earlier, the hypothesis of Fishel *et al.*<sup>4,5</sup> proposes that *B. pertussis* interferes with the beta-adrenergic receptors, thus producing an imbalance between the alpha- and beta-adrenergic receptors to the action of epinephrine. This imbalance is responsible for the increase of sensitivity to histamine and serotonin. In other words, the assumption is made that the alpha receptors become hyper-reactive to the action of epinephrine. Since, in our hands, epinephrine protected mice from histamine death, one wonders whether the interpretation given by Fishel and co-workers is entirely correct. Their hypothesis, however, has merit and should be thoroughly tested. The production of histamine sensitization by beta-adrenergic blocking agents, such as DCI and nethalide, has been confirmed in our laboratories. These agents, however, act only for a few minutes while the *pertussis* effect is long-lasting (3 weeks or longer). This investigation of the part played by medullary hormones indicates that catechol amines might be the most important hormones involved in protecting mice against histamine and that *B. pertussis* or the HSF

extracted from these cells may act by interfering with the action of these hormones. If the active substance of *B. pertussis* actually blocks some adrenergic receptors, it may prove to be an extremely powerful drug with possible practical applications. A more detailed report of these findings will be published later.

### Effect of Trypsin on Resting Potential of Frog Muscle

PAST work on the exposure of cells to protease has indicated either that the proteins on the outer surface of the cell do not contribute to the physiological properties of the membrane or that they are not available to enzymatic action. The external application of proteases to squid, lobster, or frog axons does not seem to alter the resting potential or the excitability of these cells<sup>1-4</sup>. Erythrocytes exposed to trypsin for up to 24 h show no change in permeability compared with normal cells<sup>5</sup>. However, external application of protease has been shown to produce injury potentials in muscle<sup>2</sup>.

In the work recorded here the effect of trypsin on the resting potential of single fibres of the sartorius muscle of the frog, *Rana pipiens*, was investigated. This system was chosen in order to examine the effects of protease on the electrical properties of single cells which are not surrounded by a protective cell layer, such as exists around nerve fibres. The resting potentials were measured with a standard electrophysiological recording set-up and an intracellular micropipette, the resistance of which varied from 10 to 15 M $\Omega$ . Recordings were made from fibres on the underside of the fibre bundle.

The experimental muscles were exposed to a trypsin solution (1.0 mg/ml. in frog Ringer's solution; pH 7.0-7.2) for 25 min and then washed for 5 min in normal Ringer's solution. Control muscles were left in Ringer's solution without trypsin for the same period of time. The resting potentials were recorded from 25 fibres in each muscle. Only one muscle was used from each frog in order to allow all measurements to be completed within 50 min after the frog was killed. Measurements of the resting potentials before and after treatment with trypsin were not made on the same fibres, due to the frequent occurrence of spontaneous contractions while in the trypsin solution. The trypsin solutions were made up just before their use. All experiments were carried out in August and September. The ambient temperature was 23°  $\pm$  1° C for both the treated and non-treated groups.

The results are shown in Fig. 1. The resting potentials of 100 untreated fibres ranged from 20 to 90 mV. The mean potential was 78 mV, the median 80 mV, and the standard deviation was  $\pm$  9.7. The 100 trypsin-treated fibres had resting potentials ranging from 10 to 80 mV, with a mean of 50 mV and a median of 58 mV. These resting potentials showed a bimodal distribution with the modes between 30-40 mV and 60-70 mV. Twenty fibres remaining in trypsin solution for 50 min showed an almost complete loss of resting potential, with a range of 4-20 mV. Twenty-six fibres were treated with trypsin solution which had

Fig. 1. Distribution of resting potentials. Cross-hatched bars represent the trypsin-treated fibres; dotted bars represent the non-treated fibres

been heated in Ringer's solution brought to pH 12 by sodium hydroxide. Cooling and returning the solution to normal pH by hydrochloric acid, before treating the muscle fibres, partially reactivated the trypsin<sup>6</sup>. The results of this control for enzymatic activity were a median resting potential of 70 mV and a mean of 69 mV. Because of the results of this control, complete hydrolysis of the trypsin, by refluxing in concentrated sulphuric acid, was not considered necessary.

The results of this investigation indicate that trypsin in the external medium affects the electrical properties of the muscle cell. It should be noted that this effect need not have been brought about by the hydrolysis of peptide bonds, since trypsin, like many proteases, has amino-acid amidase and esterase activity<sup>7</sup>. The bimodal distribution of the resting potentials in the trypsin-treated fibres probably represents measurements from fibres on the surface of the bundle and from fibres just below the surface layer. The latter would be exposed for less time to the trypsin, which would have to reach it by diffusion.

These results differ markedly from those on other excitable cells where the protease, applied to the outside of the cell, apparently had no effect on the resting potential. This difference could be due either to a difference in the chemical or physiological properties of the nerve membranes or the ability of the surrounding Schwann cell to act as a barrier to diffusion of protease to the axolemma. In the muscle cell, where protease has more direct access to the cell membrane, the intact state of the outer surface of the membrane does appear to play a part in maintaining membrane properties.

Lehmkuhl and Sperelakis<sup>8</sup> reported that when isolated chick ventricular tissue, which is normally quiescent, has been separated into individual cells by trypsin treatment, these cells show spontaneous electrical activity and contractions. Those authors conclude that all ventricular cells are capable of intrinsic pacemaker activity. They also reported that the isolated cells have resting potentials about 13 mV below those of cells in the intact tissue, a depolarization probably sufficient to produce the repetitive activity. As already mentioned here, the sartorius muscles often showed spontaneous contractions in trypsin solution. This depolarization and, therefore, the repetitive activity may possibly be attributed to the action of trypsin rather than to an intrinsic property of the ventricular cell which is somehow masked in the intact tissue.

## An Effect of Cyanide and Nitriles on Connective Tissue

IN the course of an investigation on a reduction in tensile strength of the skin of the rat's tail, produced by incubation in physiological saline<sup>1</sup> and thought to be due to production of acid metabolic products, the effects of various metabolic inhibitors were examined, including cyanide. This produced an increase in tensile strength which was so large and unexpected that it seemed worth further investigation.

The material used was the whole thickness of the tail cut into rings (belts) 2.5 mm wide and broken by loading stepwise at constant rate to the point of rupture. Time to rupture was 2-5 min in most cases and the same rates of loading were used for control and test samples. These rings were placed in a saline solution (modified Krebs-Ringer phosphate<sup>2</sup>) containing potassium 6 mM, magnesium 1 mM, phosphate 18 mM, sulphate 1 mM, sodium 154 mM and chloride 126 mM, the last two varying slightly with pH, to which test substances had been added. In this solution they were either incubated at 37° C for 2-3 h or more commonly left overnight at 4° C in a refrigerator and then broken in Locke's solution at 37° C.

The following is a summary of the main features of this cyanide effect.

Potassium cyanide (A.R., British Drug Houses) in concentration  $10^{-3}$  M increased the tensile strength of the whole skin at pH 7.5 by 50-100 per cent above the value for untreated rings tested immediately after removal of the tail. The minimum concentration to produce an effect was between  $10^{-5}$  M and  $10^{-4}$  M at this pH. This is the range for inhibition of many enzymes<sup>3</sup>, though for some it extends lower (for example, cytochrome oxidase,  $10^{-8}$  M).

At pH 6 with  $10^{-3}$  M potassium cyanide the effect is relatively larger, a 3-5-fold increase in tensile strength over that in saline alone at the same pH. (Without cyanide at this pH tensile strength is reduced to about one-third the untreated value<sup>4</sup>.)

The effect is on the dermis, not the epidermis, because it is found after the latter has been removed.

The effect is complete at 37° C in 1-2 h and is reversible by washing in physiological saline at approximately the same speed as it comes on in the presence of cyanide.

Methyl cyanide has a similar effect, but at concentrations about  $10^3$  higher. Ethyl cyanide has not been investigated in detail, but is less active still. The activity of methyl cyanide, together with the activity of potassium cyanide at pH 6, indicates that the effect is not due to the cyanide ion.

$\beta$ -Aminopropionitrile (fumarate,  $10^{-2}$ - $10^{-1}$  M), a substance producing lathyrism *in vivo* associated with reduction of tensile strength of tissues including skin<sup>5,6</sup>, had relatively little effect by itself but reduced the effect of cyanide. Though this antagonistic effect to cyanide is not entirely specific to lathrogenic agents it nevertheless

suggests the possibility that these might compete for sites on collagen or interfibrillary material with naturally occurring substance resembling cyanide in properties. This, however, is pure speculation.

We thank the Abbott Laboratories for a gift of  $\beta$ -aminopropionitrile.

### Linearization of Evoked Responses to Sine Wave-modulated Light by Noise

THE use of sine wave-modulated light in psychophysics<sup>1,2</sup> has directed attention to problems of linearity in the signal transmission in the visual system.

The first electrophysiological experiments with modulated light have revealed strong non-amplitude dependent distortions<sup>3,4</sup>. One of the most striking phenomena is that in most subjects with the modulation at 5 c/s a nearly pure 10 c/s response is found in the occipital leads of the EEG.

A tentative explanation was presented<sup>4</sup> in which the signal was supposed to be distorted in an early stage of the system. This distorted response, or a combination of it and a rather undistorted response, would then be processed in the cortical areas in a way comparable with selective filtering with the filter frequency set at 10 c/s. It was shown that there are subjects in which indeed resonance effects occurred at approximately 10 c/s, this being at, or near, their  $\alpha$ -rhythm frequency. It was suggested that at low percentages of modulation the quantal and neural noise may exceed the variations occasioned by the modulation.

In an earlier paper<sup>5</sup>, an estimate of the quantal noise near subjective threshold at 10 c/s was given. The conclusion was that with certain suppositions about quantum efficiency, etc., the variations in the light due to quantal noise became of the same magnitude as the amplitude of the modulation. Since this was calculated for a field of 22', it can be expected that for one single receptor the modulation-noise ratio will be considerably smaller. Although such estimates are open to criticism, it was suggested that in a case where the noise exceeds the actual signal, in some non-linear systems the distortion would disappear. This leaves the question open whether and in what way the signal-to-noise ratio in the actual case will have to be improved before the stage of distortion is reached, regarding the large distortions found at modulation depths as low as 3 per cent.

For a number of non-linear systems of the rectifying type the influence of noise on the response functions was calculated and it was found that a sine wave with noise or a non-correlated periodical signal, such as a triangle, sine wave, etc., added, will be less distorted by rectification procedures than a pure sine wave.

This suggested the following experiment: A well-trained subject was stimulated with white light from a television projection tube which could be modulated electronically<sup>6</sup>. The stimulation was performed with a large field at moderate intensity, in the range of 50–200 lux equivalent. The level of illumination had little influence on our results. The responses of the subject for 10 per cent modulation were averaged by a CAT computer and are presented for

Fig. 1. Occipital responses to 5.6 and 11.2 c/s. Diffuse illumination. 10 per cent modulation, natural pupil, approximately 200 lux equiv. Upper trace: modulated light. Medium trace: responses to sinusoidal stimulation (A and B). Lower trace: responses to sinusoidal stimulation and noise (C and D).

two-eye stimulation in Figs. 1A and B for 5.6 and 11.2 c/s. It is seen that the 5.6 c/s gives a pure second harmonic response, whereas the response at 11.2 c/s displays mainly the fundamental frequency. If now gaussian noise resulting in a signal-noise ratio  $A^2/2\sigma^2 = 0.04$  ( $A$  being the amplitude of the sine wave,  $\sigma$  being the standard deviation of the noise) and a band-width 15–25 c/s is added to the modulating signal (1C and 1D) the second harmonic at 5.6 c/s stimulation nearly disappears, whereas the fundamental response at 11.2 c/s stimulation is much less affected, if at all. This may depend on the influence of saturation phenomena.

If one eye is stimulated with the sine wave modulation and the other eye separately at the same time with only noise, not much change in the responses to 5.6 and 11.2 c/s is found, compared with responses to stimulation of one eye with sine wave modulation and the other eye with steady light. This, and other arguments, suggest that most probably the distortion is not caused at a late stage in the system. If these results are valid also for the spontaneous noise inherent in the retinal processes, a kind of integration has to be assumed to increase the signal-noise ratio before the distorting stage is reached.

The possibilities for further work with this method are evident, and one of these is the adding of high-frequency sine waves to get an impression of the high-frequency attenuation up to the stage of distortion. By comparing responses at 5.6-c/s stimulation with the addition of non-related high-frequency sine waves we could deduce that the high-frequency attenuation from 25 to 60 c/s is less than would be expected from the so-called De Lange curves, a problem discussed earlier by Van der Tweel<sup>7</sup> and Levinson<sup>2</sup>.

## PHARMACOLOGY

## Antitussive Activity of Medazonamide

Most of the known antitussive agents also possess, in varying degree, other pharmacological properties, such as the analgesic, antihistaminic, local anaesthetic and spasmolytic ones (Silvestrini and Maffii<sup>1</sup>). These activities are often responsible for, or directly connected with, specific clinical side effects that may limit the effect. In particular, the antitussives that show analgesic effect produce depression of respiration and possibly tolerance, while antihistaminic antitussives often lead to drowsiness, and the local anaesthetic ones usually have a high toxicity.

For these reasons the search for new agents, possessing almost exclusively antitussive properties, is still pursued in many pharmacological laboratories. In the course of a systematic investigation on a new series of pyridazine compounds which have been prepared by Teotino and Cignarella<sup>2</sup>, it appeared that 2-methyl-4,5-dihydro-3-pyridazinone-6-carboxamide ('medazonamide') possesses antitussive properties in doses that do not produce any other pharmacological effect. Moreover, medazonamide was found to be practically non-toxic both in acute and chronic tests.

Medazonamide depresses and inhibits the cough induced in guinea-pigs by inhalation of acrolein vapours according to a method previously described<sup>1</sup>. Median effective doses and acute toxicity of medazonamide and some other known antitussive agents are given in Table 1.

Table 1. ANTITUSSIVE ACTIVITY (GUINEA-PIGS) AND ACUTE TOXICITY (MICE) OF MEDAZONAMIDE AND OTHER ANTITUSSIVE AGENTS

Compounds	Cough inhibition $ED_{50}$ (mg/kg s.c.)	$LD_{50}$ (mg/kg) s.c.	$LD_{50}$ (mg/kg) i.v.
Codeine HCl	4	370 (ref. 3)	80 (ref. 3)
Morphine sulphate	5	311 (ref. 4)	255
Narcotine	3-5	390 (ref. 5)	—
Dextromethorphan	6	275 (ref. 3)	37 (ref. 3)
Benzononatine	3	230 (ref. 6)	9 (ref. 6)
Medazonamide	5	>1,000	>1,000

Medazonamide, at doses of 5 mg/kg subcutaneously, or 20 mg/kg orally, exerts inhibitory activity on coughing induced in dogs by aerosol of  $H_2SO_4$  (0.5 N), according to the method described by Winter and Flataker<sup>7</sup>.

Appreciable analgesic activity free from sedation is shown only at doses of 50 and 100 mg/kg subcutaneously and intraperitoneally in rats (method described by Randall and Selitto<sup>8</sup>) and mice (Eddy and Leimbach<sup>9</sup>). An intraperitoneal dose of 500 mg/kg of medazonamide produces significant inhibition of formalin-induced oedema of the rat hind-paw.

Frequency and amplitude of respiration are not modified after intravenous injection of 10 mg/kg of medazonamide in rabbits (anaesthetized with chloralose, 50 mg/kg intraperitoneally, and ethyl urethane, 1 g/kg subcutaneously) or after subcutaneous administration of 20 mg/kg in rats (anaesthetized with phenobarbitone, 120 mg/kg intraperitoneally). Arterial blood pressure of dogs (anaesthetized with pentobarbital sodium) is not changed by intravenous doses of 5 and 10 mg/kg.

At intravenous doses of 5 and 10 mg/kg medazonamide does not produce bronchial spasm in guinea-pigs. Codeine elicits bronchial spasm at doses of 7 mg/kg subcutaneously and 3-5 and 10 mg/kg intravenously.

At concentrations up to 10  $\mu$ g/ml. medazonamide is without any spasmolytic effect on contractions of isolated small intestine, induced either by barium chloride or acetylcholine (rat) or by histamine (guinea-pig).

Acute toxicity of medazonamide is extremely low (see Table 1). In fact, it causes no deaths in mice even after administration of 1 g/kg by various routes, and it differs, therefore, from all other known antitussive drugs, including the most recently discovered ones<sup>10,11</sup>.

In subacute and chronic toxicity tests, carried out in dogs at daily oral doses of 200 and 100 mg/kg for 4 weeks and 6 months respectively, medazonamide has been shown

to be well tolerated and free from side-effects even at high dose-levels and over prolonged treatment periods.

The results of the afore-mentioned pharmacological investigation demonstrate that medazonamide is an effective antitussive agent practically devoid of any pharmacological side-effects.

An extensive clinical study has shown that medazonamide significantly reduces the cough caused by chronic bronchitis in man (Nicolis and Pasquariello<sup>12</sup>). In 'double blind' conditions a dose of 800 mg of the substance appeared to be as effective as 60 mg codeine. The lack of any side-effect in man has been confirmed also for doses much higher than the effective ones.

## Chloroquine in Dextran Oedema

EXPERIMENTS in our laboratory have shown that chloroquine blocks the actions of endogenous as well as exogenous histamine in guinea-pigs<sup>1</sup>. Chloroquine in these experiments was also found to block the action of exogenous 5-hydroxytryptamine (5HT). Further experiments were undertaken to study the action of chloroquine on the endogenous 5HT, which has been shown by several workers to be released by dextran in rats and mainly accounts for the oedema<sup>2,3</sup>. The cholesterol content of the adrenal glands of these rats was also estimated to determine whether the adrenals were involved in the action of chloroquine on dextran oedema.

A group of 10 male albino rats (100-150 g) were injected daily with chloroquine sulphate (10 mg/kg) intramuscularly. An equivalent amount of normal saline was injected into a similar group of 10 control rats. On the 31st and 38th day each animal was injected intraperitoneally with 1 ml. of 6 per cent dextran solution per 100 g body-weight. The dorsoplantar thickness was measured by means of a calliper rule as described by Setnikar *et al.*<sup>4</sup> to assess the degree of oedema. The animals were killed on the 45th day and the adrenal glands were removed. Total cholesterol was estimated by means of the Lieberman-Burchard reaction<sup>5</sup>. Results are summarized in Table 1.

It is seen from the table that chloroquine causes a reduction in the dextran oedema. That the oedema is not completely prevented shows a partial antagonism to the endogenous 5HT. These results are in conformity with *in vitro* results<sup>1</sup>. Chloroquine was found to cause a slight

Table 1. EFFECT OF CHLOROQUINE ON DEXTRAN OEDEMA AND ADRENAL CHOLESTEROL IN RATS

	Mean increase in dorso-plantar thickness (mm) $\pm$ (S.D.)	Mean cholesterol content of adrenals (g/100 g) $\pm$ (S.D.)
Control	2.33 $\pm$ 0.33 (2.0-3.0)*	2.66 $\pm$ 0.55 (1.87-3.02)
After chloroquine	0.87 $\pm$ 0.57 (0.0-1.5)	3.87 $\pm$ 1.03 (1.95-7.43)

## Phenazine Methosulphate in Cyanide Toxicity

THE blocking action of cyanide ion on cellular respiratory enzyme cytochrome oxidase is of considerable biological importance. *In vitro* action of phenazine methosulphate<sup>1</sup> (PMS) appears somewhat similar to that of the terminal respiratory enzymes in the cell. The following experiments would suggest that PMS might be effective, *in vivo*, as a temporary substitute of the cyanide-blocked respiratory enzymes.

Adult albino rats and mice of either sex were used. All substances were dissolved in water and used within 3 h. PMS solution was protected from light by thick black paper. Respiratory arrest in animals was taken as the end-point.

The dose of PMS (15 mg/kg) used in these experiments was apparently well tolerated by rats and mice. Sodium cyanide (10 mg/kg) alone invariably killed all animals. In mice, 15 mg/kg of PMS proved more effective than 7.5 mg/kg. Increasing the interval between PMS and cyanide injections from 0.25 min to 4 min decreased the protecting action of PMS. Those animals which PMS or nitrite failed to protect against cyanide lived longer than the ones receiving only cyanide. PMS solution lost considerable activity after 3 h exposure to daylight. Animals protected by PMS or nitrite against cyanide often suffered brief unconsciousness followed by sedation. Animals surviving for 2 h usually recovered completely. In rats, PMS given by the intraperitoneal route 3 min after subcutaneously injected cyanide could protect 69 per cent of animals.

Table 1. SURVIVAL OF MICE AND RATS AFTER CYANIDE TREATMENT, WITH AND WITHOUT PROTECTIVE PRE-TREATMENT

First drug (mg/kg)	Interval between first and second drug (min)	Second drug (mg/kg)	No. animals died and average survival time (min)	No. and % of animals protected against cyanide
Mice				
NaCN, 10	Nil	Nil	24 (3)	Nil (0%)
PMS, 15	0.25	NaCN, 10	8 (35)	22 (73%)
PMS, 15	4	NaCN, 10	5 (19)	1 (17%)
PMS, 7.5	0.25	NaCN, 10	6 (24)	4 (40%)
PMS, 15*	0.25	NaCN, 10	7 (35)	Nil (0%)
NaNO <sub>2</sub> , 80	4	NaCN, 10	4	11 (73%)
Rats				
NaCN, 10	Nil	Nil	20 (15)	Nil (0%)
NaCN, 10	3	PMS, 15	8 (29)	18 (69%)

\* PMS solution in glass container exposed to daylight for 3 h. NaCN injected into rats by the subcutaneous route. All other injections by the intraperitoneal route. Room temperature 16°–34° C.

Sodium nitrite, the well-known antagonist of cyanide *in vivo*, was used for comparison. It acts by converting haemoglobin into methaemoglobin; the latter forming the comparatively stable complex cyanmethaemoglobin. Unlike PMS, nitrite was effective when injected 4 min before cyanide. This suggests that its mode of action is different. Survival of 73 per cent of mice and 69 per cent of rats suggests what is otherwise an invariably fatal dose of cyanide is considered significant.

## Nitrogen Oxides in Tobacco Smoke

BECAUSE of their considerable pharmacological significance, the presence of nitrogen oxides in tobacco smoke has been the subject of a number of reports in the past few years<sup>1–4</sup>. In general, the choice of experimental techniques has been such that the relative amounts of the principal components, nitric oxide (NO) and nitrogen dioxide (NO<sub>2</sub>), in cigarette smoke have not been clearly established.

Although NO and NO<sub>2</sub> are both readily absorbed in the human lung, their physiological action is reported to be quite different. NO is found to be approximately five times less toxic than NO<sub>2</sub> (ref. 5), and recently it has been found that NO is approximately six times less active as a mammalian ciliastatic agent<sup>6</sup>. These considerations made it desirable to develop an analytical technique which would provide quantitative estimates of the amount of each oxide in tobacco smoke. With such a technique it is found that almost all of what had previously been considered as a mixture of oxides is, in fact, the less active nitric oxide.

Although NO undergoes oxidation to NO<sub>2</sub> by the well-known termolecular reaction  $2\text{NO} + \text{O}_2 \rightarrow 2\text{NO}_2$ , the rate of conversion is found to be relatively slow at the concentrations existing in cigarette smoke. It is calculated that approximately 500 sec would be required in undiluted smoke, and more than 5,000 sec would be required in the more dilute system within the human lung, for the oxidation of half the NO to NO<sub>2</sub>. Since these times are very much greater than those available during the inspiration, absorption and expiration of a puff of smoke, NO can be considered as an independent agent in its pharmacological action.

Because of the considerable difference in volatility of NO (B.P. –151° C) and NO<sub>2</sub> (B.P. 21° C), a cold adsorption trap can effectively be used to separate these gases. Following such a separation the NO is allowed to oxidize to NO<sub>2</sub>, and the concentrations of both are individually estimated by the Saltzman procedure<sup>7</sup>. Our smoking and smoke collection system consisted of a train containing an efficient particulate smoke filter, a flow-limiting orifice, a small U trap, and an evacuated terminal gas collection flask. The functions of the filter, orifice and terminal flask have been described elsewhere<sup>8</sup>, and it is necessary to note here that they provide a means of withdrawing a single 40-ml. puff of smoke of normal duration from a lighted cigarette, and of separating the gaseous mixture from the entrained smoke particles. The 55-ml. terminal collection flask both provides the suction necessary for puffing and also serves as a quantitative container for the gas mixture and its component NO during the reaction with 10 ml. of the Griess-Ilosvay reagent contained therein. The 7-ml. U trap, which is packed with glass helices and 1.0–1.5 grams of silica gel deactivated with 20 per cent H<sub>2</sub>O, is cooled to dry-ice temperatures. This trap largely retained such NO<sub>2</sub> as is present, which subsequently can be estimated by elution and reaction with Griess-Ilosvay reagent.

Experiments with pure gases and mixtures of NO and NO<sub>2</sub> each diluted with nitrogen to the approximate level of nitrogen oxides in cigarette smoke were performed. It

Table 1. NITROGEN OXIDE CONTENT OF CIGARETTE SMOKE

Cigarette	Gas in U trap ( $\mu$ l./puff)	Gas in flask ( $\mu$ l./puff)	NO		NO <sub>2</sub>		Total	
			( $\mu$ g/puff)	(p.p.m.)	( $\mu$ g/puff)	(p.p.m.)	( $\mu$ g/puff)	(p.p.m.)
Non-filter (fourth puff)	4.9	22.7	38.2	715	0	0	38.2	715
Filter, A (fourth puff)	3.1	14.2	24.0	442	0	0	24.0	442
Filter, B (lighting puff)	5.0	22.2	37.4	698	0	0	37.4	698
(fourth puff)	5.7	27.6	46.6	871	0	0	46.6	871
(last puff)	5.8	31.8	54.0	1,008	0	0	54.0	1,008
(fourth puff, whole smoke)	5.6	24.4	41.2	768	0	0	41.2	768
Filter, C (fourth puff)	7.4	24.3	40.5	755	1.2	25	41.7	780

was found that the U trap captured 79 per cent of the NO<sub>2</sub> introduced, while 77 per cent of the NO passed into the terminal flask. Overall recoveries of 90–99 per cent of the two gases were achieved, the slight losses probably occurring through irreversible absorption of some of the gases on silica gel and during the manipulations required in the analytical procedure. Utilizing the pure gas data, simultaneous equations were formulated which were used to resolve the NO and the NO<sub>2</sub> concentrations in gas mixtures and cigarette smoke. Applying these to 9:1, 3:2 and 1:1 molar mixtures of NO and NO<sub>2</sub> resulted in good agreement between the predicted and observed quantities of gas in the two traps.

With this smoking and trapping system, individual puffs of cigarette smoke were analysed and the division of nitrogen oxides calculated by the equations. Table 1 summarizes data obtained on representative puffs from several 'king-size' filtered and unfiltered cigarettes. Measurements of initial, intermediate and final puffs on these and other cigarettes, and with and without the smoke filter in the system, give essentially the same one-sided division of these oxides. From these data, it is clearly indicated that essentially all the nitrogen oxides in fresh, normally obtained cigarette smoke are the less pharmacologically active nitric oxide, and that nitrogen dioxide is present at most only in trace quantities.

The almost complete absence of nitrogen dioxide in the mainstream of cigarette smoke may stem from several factors. One is that during the formation of nitrogen oxides in the hot reducing atmosphere close behind the glowing cone, conditions favour the formation of the lower oxides. Elkins's<sup>9</sup> and Tada's<sup>4</sup> data on the NO and NO<sub>2</sub> contents of fumes from various combustion sources show this to be the general case. Another factor tending to eliminate such NO<sub>2</sub> as might be formed is the presence of moisture and reactive organic materials in the smoke stream and tobacco column, which can absorb and react with NO<sub>2</sub>.

## IMMUNOLOGY

### *In vitro* Studies on Homograft Sensitivity

THE migration of cells from capillary tubes in tissue culture chambers has proved valuable in studies on delayed hypersensitivity in guinea-pigs<sup>1,2</sup>. Using this technique, it was observed that inhibition of migration of peritoneal cells from guinea-pigs with delayed hyper-

sensitivity to tuberculin and other protein antigens occurs only in the presence of the specific antigen. On the other hand, peritoneal cells from guinea-pigs producing circulating antibody were not inhibited by the corresponding antigens.

With this information at hand we have adapted this technique of peritoneal cell migration to the study of the homograft reaction in inbred strains of mice. We find that peritoneal cells from mice with homograft sensitivity are inhibited when mixed with peritoneal cells obtained from the strain of mice that had donated the sensitizing skin homografts. Furthermore, peritoneal cells obtained from unrelated strains of mice, when mixed and placed in tissue culture chambers, migrate well together without inhibiting each other.

The mice used in this study (*A/Jax*, *CBA* and *C57BL/6*) were obtained from Jackson Memorial Laboratory, Bar Harbor, Maine, and were 3 months old at the time of the experiment. The donors of sensitizing skin grafts were *A/Jax* mice and the recipients were *CBA* mice.

The sensitizing skin grafts were suprapannicular, circular, 11 mm in diameter. They were fitted grafts and were applied to the lateral thoracic regions. The grafts were covered with non-adhering dressing and wrapped with latex bandage and adhesive tape. Peritoneal exudate cells were collected in cold Hank's solution 3–4 days after the intraperitoneal injection of 3–4 ml. of sterile light mineral oil. Sensitive peritoneal cells were collected from the homograft recipients following the rejection of the sensitizing skin grafts. The cells were suspended in Eagle's culture medium containing 15 per cent normal guinea-pig serum, then packed in capillary tubes and placed in tissue culture chambers as previously described<sup>3</sup>. When cells from two strains were mixed, equal proportions were used. Tissue culture chambers were incubated at 37° C for 24 h and the area of cell migration from each capillary tube was measured by planimetry. Percentage migration of cell mixture was calculated as follows: average migration of mixture of cells multiplied by 10 and divided by average migration of normal and sensitive cells separately.

Table 1. MIGRATION OF PERITONEAL CELLS FROM NORMAL AND SENSITIVE *CBA* MICE IN THE PRESENCE OF CELLS FROM THE SENSITIZING STRAIN *A/Jax*

No. animals pooled	Percentage migration		
	<i>CBA</i> Sensitive to <i>A/Jax</i> + <i>A/Jax</i>	Normal <i>CBA</i> + <i>A/Jax</i>	<i>CBA</i> Sensitive to <i>A/Jax</i> + <i>C57BL/6</i>
15	56		
15	55		
15	70		
20	55		101
15		106	
16		100	
15		97	

It can be seen from Table 1 that inhibition of migration occurred in all the experiments where cells from sensitive *CBA* mice were mixed with cells obtained from *A/Jax* mice (the sensitizing strain). The specificity of the inhibition observed is illustrated by the normal migration of cells from *CBA* mice with homograft sensitivity to *A/Jax* strain in the presence of cells from *C57BL/6* (unrelated to *A/Jax*).

In this system the populations of cells comprising the mixture are functioning as antigen and sensitized cells

in addition, both are viable and capable of migration. Thus, the observed inhibition of migration may be due to an effect on either of the populations in the mixture or a composite effect on both.

Since peritoneal cells from the donor of the sensitizing skin homografts have transplantation antigens, the observed inhibition of migration could be an effect of cellular antigens (residing in or on the donor cells) on sensitive lymphoid cells. In this context the inhibition may be similar in nature to the effect of tuberculin or ovalbumin on sensitive peritoneal cells obtained from guinea-pigs with delayed allergy to these antigens. The homograft model, however, differs from the delayed allergy system in the use of viable cells as antigen in contrast to soluble antigens such as tuberculin.

On the other hand, it is possible that the inhibition observed is due to the damaging action of sensitive peritoneal lymphoid cells on cells obtained from the sensitizing strain interfering with their migration. This possibility could place the reaction in the class of target cells affected by sensitive lymphoid cells in other systems<sup>3</sup>.

What cannot be excluded is the possibility that the inhibition of migration may be the result of the two mechanisms discussed above operating simultaneously. Thus peritoneal cells from the donor and recipient of the skin homograft may be affected simultaneously.

In its gross appearance and temporal behaviour the migration of mouse peritoneal cells is similar to the migration of peritoneal exudate cells obtained from guinea-pigs<sup>2</sup>. Furthermore, under the conditions of the present experiment (24 h observation) peritoneal cells from one strain of mice do not exert any inhibitory effect on the migration of peritoneal cells from a genetically different strain of mice (for example, *CBA + A/Jax*, *CBA + C57BL*). This is of interest since the cells are in close contact and both populations are immunologically competent.

This work was supported in part by a grant from the Institute of Allergy and Infectious Disease, U.S. Public Health Service, A1-01254, and by the Streptococcal and Staphylococcal Disease Commission of the U.S. Armed Forces Epidemiological Board.

### Studies of Group Agglutinogens of *Staphylococcus aureus*

THE serological differentiation of staphylococci has been the subject of many investigations since the preliminary work of Cowan<sup>1</sup> which divided coagulase-positive staphylococci into three main groups according to slide agglutination reactions with adsorbed antisera. Most of the serological reagents appear to be active against various type-specific antigens, and strains are usually classified according to a pattern of reactions. Recently, Haukenes demonstrated that a number of antisera in Oeding's serological typing system<sup>2</sup> were actually complexes of different antibodies<sup>3-5</sup>. Moreover, by small changes in the

Fig. 1

adsorption schemes, Haukenes has succeeded in preparing some 15 or 20 serological reagents, most of which are useful for typing staphylococci.

Despite the new knowledge of type-specific antigens in *S. aureus*, means for the identification of group-specific antigens are still quite rudimentary. Most of the progress in this direction in recent years has been made by examination of so-called normal sera and by serum-gel diffusion. In 1958, Jensen<sup>7</sup> reported a group antigen from *S. aureus* which he called antigen A. Cohen *et al.*<sup>8</sup> identified another antigen (recently referred to as RL antigen<sup>9</sup>) by serum-gel diffusion with pre-immune rabbit serum. Antibody to this antigen has been found also in normal human, guinea-pig, hamster and mouse sera (including serum from germ-free mice). Recent work by Haukenes *et al.*<sup>10</sup> has resulted in the redefinition of polysaccharide A of Julianelle and Wieghard<sup>11</sup>. Polysaccharide A has been identified by serum-gel diffusion and appears to be immunologically identical with the main teichoic acid of *S. aureus*<sup>10</sup>.

When rabbits are immunized with a strain of *S. aureus*, the antiserum before adsorption usually reacts with most strains, and slide agglutination titres as high as 1:5,000 are not uncommon. The cross-reactions of a staphylococcal antiserum could be due to a single antigen present in the majority of strains or to a complex of antigens which vary from strain to strain. Results of a study of antiserum for strain 629-3 indicated that the so-called group agglutino-gen of *S. aureus* is actually a complex.

Strain 629-3 was isolated from a patient at the U.S. Public Health Service Hospital, San Francisco, California. The culture was submitted to the Communicable Disease Center for phage typing and was found to be phage type 53/83 and serotype *en*. Because of the apparent absence of other known typing factors, the culture was considered to be an interesting one for use as an immunizing strain.

The slide agglutination titres of serum 629-3 for the type strains are shown in Fig. 1 (first part). There was considerable variation in observed titre from strain to strain. Titres for some of the heterologous strains such as Cowan I were a good deal higher than that for the homologous strain. The low titres for strains Wood 46 and Cowan II are interesting because these strains are generally unreactive with 'normal' sera and appear to lack some part of the group antigens of *S. aureus*.

Cross-adsorption experiments were performed with some of the type strains. After serum for 629-3 was adsorbed with strain 28, considerable activity remained. Strain 28 has the serotype *aben*, and it had been predicted that this strain would clear 629-3 serum of all agglutinating

activity for *S. aureus*, since strain 28 has all the known typing antigens found in strain 629-3.

Further adsorptions were carried out with this serum (629-3-abs.-28; see Table 1). Strains Cowan II, Wood 46, and 28 did not remove any more agglutinating activity. The other type strains removed most of the activity. The most surprising result was that obtained when the serum was adsorbed with the homologous strain. Rather than clearing the serum, 629-3 adsorption caused little change in the reaction spectrum. After adsorption with the homologous strain, there was no further agglutination of 629-3, but heterologous strains such as Cowan I and S365 agglutinated strongly. Apparently strain 629-3 stimulated production, in rabbits, of an antibody with which it neither reacts in agglutination tests nor removes in adsorption tests.

This experiment was repeated using twice as many cells for the adsorption, and then adsorbing again with the same number of cells. The central part of Fig. 1 shows the agglutinating activity left after this heavy adsorption with the homologous strain. Adsorptions with boiled and with autoclaved cells did not remove this agglutinating activity. The factor delineated here has been tentatively called the 629-G factor.

Pre-immune serum from both rabbits used for 629-3 immunization was tested for agglutinating antibodies with the type strains. Only strains Cowan I, S365, and 17A agglutinated. The titres were low; the activities were similar to those found in other non-immunized rabbits. The antibody present in 629-3 immune serum after adsorption with the homologous strain could not be accounted for by the antibody level in pre-immune serum.

When 210 other cultures of *S. aureus* were tested for agglutination in the 629-G factor, 65 were positive and 145 negative. Some of the cultures which failed to agglutinate could adsorb 629-G antibodies.

An attempt was made to prepare 629-G factor from one of the type strains. Serum for 1503, type *aemn*, was adsorbed with strains 28 and 629-3. The resulting antiserum did not agglutinate strains Wood 46, 28, Cowan II, and 629-3. However, when this serum was compared to 629-3 (by agglutination tests with miscellaneous *S. aureus* cultures), it exhibited a wider spectrum of reaction. When the adsorbed 1503 serum was diluted 1:400 it reacted predominantly with cultures which reacted strongly in the 629-G serum. Another sample of 1503 serum from the same rabbit, taken at a later bleeding, was adsorbed with strains 28 and Cowan II. This serum reacted in parallel with 629-3 serum adsorbed with 629-3 only, when 44 cultures were tested in both antisera.

The data indicate that: (1) 629-G factor is a part of the group agglutinin complex of *S. aureus*, and (2) other antigenic factors must be responsible for a portion of the reaction spectrum observed with unadsorbed staphylococcal antisera. These results suggest that the 'group' agglutinin of *S. aureus* is a complex, and that the competency of an adsorbing strain for the production of specific factor sera depends on its ability not only to adsorb those specific antibodies for antigens expressed in

its formula, but also to adsorb certain undesigned group agglutinins.

## PATHOLOGY

### Role of Splenomegaly in Tumour-bearing Mice

MANY attempts have been made to explain the presence of splenomegaly in tumour-bearing mice. Early work by Andreini<sup>1</sup> *et al.*, in mice bearing homografted tumours, demonstrated splenomegaly which was interpreted as evidence of immunological activity against the tumour. When splenomegaly was found in the isologous situation the interpretation was made again<sup>2</sup> that this was a sign of a response of the mouse to a cancer-specific antigen in the tumour and this antigen might be lost on transplantation. Stuart and El Hassan<sup>3</sup> have recently shown the protective effect of isologous spleen cells from tumour-bearing mice with splenomegaly, injected locally with the Landschütz ascites tumour. In the experiments reported here I have attempted to demonstrate the protective influence of the splenomegaly by transferring spleen cell suspensions from tumour-bearing mice to isologous mice challenged with the same tumour.

An inbred colour of A strain mice was used. An A strain mammary tumour *AMT*<sub>1</sub> was transplanted by subcutaneous injection of a standard dose of tumour cells. Spleens were weighed from normal mice and from mice bearing tumours for different intervals and after injections of cell-free extracts of the tumour. The results shown in Table 1 confirm the presence of increasing splenomegaly with tumour growth. This splenomegaly has not been demonstrated after transfer of cell-free extracts of the tumour.

Table 1. SPLEEN WEIGHTS WITH TUMOUR GROWTH

Group	Spleen weight (mg)
Normal mice	120
Mice with 2-day tumour	128
Mice with 7-day tumour	229
Mice with 14-day tumour	249
Mice with 19-day tumour	450
Mice with cell-free extract	130

To investigate the apparently protective effect of the splenomegaly, spleens were taken from mice bearing tumours for 2, 7 and 14 days. Spleen cell suspensions were prepared as described by Woodruff and Symes. Cells were incubated in 0.05 per cent aqueous trypan blue for 10 min and, if less than 10 per cent of the cells stained, they were used for injection. The suspensions were injected slowly into the tail vein of the mouse at a dose of one spleen to a mouse in 0.5 ml. Medium 199. The spleen cells were injected 24 h after the subcutaneous injection of a standard dose of tumour. Groups of eight mice were used and control groups received tumour only. Tumour diameters were measured daily in two planes and the areas calculated. The measurement of the tumours showed clearly no difference in tumour size between the

experimental and control groups. Histological sections stained with haematoxylin and eosin showed no difference between the groups and no evidence of increased lymphocytic infiltration was seen. Finally, spleen cells and tumour cells were injected together subcutaneously in the same dose. Control mice received spleen cells from normal mice and the results again showed no difference in tumour size between treated and control groups.

Immunological attack on tumours depends on antigenic differences between cancer tissue and normal tissue. There is extensive evidence for cancer antigens in certain tumours<sup>4</sup>. However, in many experimental situations the cells have been sensitized to antigenic differences between tumour and host and not to any cancer-specific antigens. Woodruff and Symes<sup>2</sup> have proposed that splenomegaly seen in early transplants of spontaneous tumour was indicative of an antibody response to an antigen which is lost on subsequent transfer. If the splenomegaly seen here with transplantable tumour has the same explanation, then transfer of spleen cells from tumour-bearing mice should influence the growth of the tumour in new hosts. This has not been the case. This may be because this tumour may not possess, or has lost, a strong cancer antigen. Alternatively the splenomegaly seen may not indicate an immune response. Splenomegaly in mice is seen after injection of extracts of cancer tissue or toxohormone<sup>6</sup>, and this has been shown in certain cases to be due to bacterial or viral colonization of the tumour<sup>6</sup>. Old<sup>7</sup> has described splenomegaly after transfer of a virus particle in a cell-free extract of an experimental tumour, but this has not been seen in this situation.

Finally, the transferred immunologically competent cells may be in a state of immunological depression caused by the tumour, comparable to the depressed state seen in human cancer cases<sup>8</sup>. It is clear that splenomegaly in this situation does not indicate an effective transferable response by the host and further investigation is required to elucidate the true mechanism.

This work was carried out during tenure of a fellowship from the British Empire Cancer Campaign for Research. I thank Dr. D. Tee for supply of the tumour and Prof. J. G. Murray and Mr. H. C. Edwards for advice.

## Origin of the Sickling Gene

SICKLING was first observed in an American Negro<sup>1</sup>. Many reports on the frequency of the sickle cell trait in various populations soon followed, and from them the conclusion was drawn that the black Negroes of the Central African Belt were the focus of this haemoglobin variant.

Recently, however, migrations from Asia to prehistoric Africa and not *vice versa* were thought more likely to have happened. This was based on: (a) the observation that the tall, broad-shouldered skeleton of the modern African Bantu appears only in Neolithic excavations, whereas the types found in older strata are more slender; and (b) on similarities in certain African and some Indian cattle and poultry<sup>2</sup>. It was later suggested that sickling was a Veddoid feature, and that it was from a

group of these people who lived in Arabia in Neolithic times that the sickling gene had spread both to Africa and to India<sup>3,4</sup>. The Veddoids are primitive tribes whose features have been traced in India, South Arabia, Persia, Egypt, Sardinia and Monaco<sup>3</sup>. In Arabia the Veddoids differ from the present-day inhabitants<sup>4</sup>.

In our opinion, the common single origin of the sickling phenomenon in the Near East remains to be substantiated. In the first place, sickling is rare in the pure Arabs or Bedouins<sup>4</sup>, and it is difficult to explain this finding unequivocally when these have been in a closer and longer geographical contact with the Veddoids in Arabia and their assumed sickle cell gene. Secondly, sickling is absent from some other Veddoid populations<sup>3</sup> and is not present in any outstanding incidence in other places where Veddoid remains have persisted, for example, in Egypt, Monaco and Sardinia. Thirdly, no spread of other genetically-determined Veddoid characteristic, for example, blood groups, has been reported parallel to that of the sickling gene. Fourthly, slavery introduced to the Near East great numbers of Negroes from Africa, whose role in the spread of the sickle cell gene has not been fully assessed.

It is interesting to note that sickling is not restricted to human beings only but is to be observed in the blood of rackitic white rats and experimentally in guinea-pigs<sup>5</sup>, and also in the white-tailed deer<sup>6</sup>. The distribution of different pigments is not unequivocally racial. A germane suggestion was recently made by Clément about the thalassaemic syndromes<sup>7</sup>. It is no longer conceivable that thalassaemia is an exclusive disorder of the Greco-Roman races, and haemoglobin variants have spared no race.

## Assessment of Non-emergence of Drug-resistant Strains of Pathogens treated with Polynoxylin

THE difficulty of inducing drug-resistance of micro-organisms to polynoxylin has previously been reported<sup>1,2</sup>. Since July 1960, 360 bi-weekly sub-cultures of the organisms listed in Table 1 have been made.

Initially, attempts were made to render organisms 'insensitive' by the addition of small amounts of polynoxylin to large volumes of broth cultures. The mixture was thoroughly shaken and re-incubated and, after three days, large volumes of the treated broth were sub-cultured. Growth of sub-culture was obtained for the first month or two, but gradually 'tailed off'.

In the first experiments 100 ml. of nutrient broth was used; 0.4 mg of polynoxylin powder was placed at the

Table 1. TEST ORGANISMS FOR WHOLE SERIES

<i>S. aureus</i> , coag. positive	Sensitive to all antibiotics
<i>S. aureus</i> , coag. positive	Insensitive to penicillin
<i>S. aureus</i> , coag. positive	Insensitive to tetracycline
<i>S. aureus</i> , coag. positive	No. 7
<i>S. albus</i>	Nos. 2, 7, 8
$\alpha$ Haemolytic streptococci	Nos. 1, 3, 4, 5
$\beta$ Haemolytic streptococci	Nos. 2, 8, 9
'Indifferent' streptococci	3 types
<i>E. coli</i>	Nos. 3, 4, 6, 7, 8, 11, 12, 13
Pneumococci	No. 4
Mixed oral organisms	No. 2
<i>Pyocyanus</i> spp.	Nos. 1, 3
<i>Proteus</i> spp.	Nos. 2, 3, 4, 5
<i>B. subtilis</i>	No. 1
<i>Corynebact.</i> spp.	No. 1

bottom of a sterile culture bottle, to which the medium was slowly added so as not to disturb the powder. A standard loopful of a 24-h culture was added to the top of the medium without shaking and incubated at 37° C for three days, when a loopful of the growth from the 'top-layer' was plated and tested for sensitivity using the disk-method. Five drops were added to a similar PPI-treated broth. Eventually, in two or three months, the cultures died out.

A plate and disk-method was also used. The test organisms were plated out on solid media and a suitable polynoxylin sensitivity disk was placed on the moist media. After incubation for three days, standard loopfuls were removed from (a) the centre of the clear zone of inhibition; (b) the outer ring of the clear zone of inhibition; (c) the outer periphery of the zone, and (d) the junction of the zone of inhibition and growth. These were inoculated into broth and on to solid media.

No growth was ever obtained from inocula carefully taken from (a) and (b). In many cases inocula from (c) produced growth. Inocula from (d) always produced growth. No insensitive organism has emerged.

It has been reported that *Proteus* and *Pyocyanea*, when tested by the disk-method, show, on drying for periods longer than a week, some 'creep' of the organisms across the inhibition zone. I have observed this in four cases (two of each). The 'creep' colonies have been tested on repeated sub-culturing and are still sensitive to polynoxylin.

It is clear that polynoxylin is only active in the presence of water<sup>1-3</sup>. A neat demonstration of this is available by blowing pure polynoxylin powder through a 'Freon' aerosol. Cultures of *Staphylococcus aureus*, treated with the polynoxylin immediately after propulsion, show no inhibition when sub-cultured more than 5 min, up to 1 h. After this period of time, growth is somewhat inhibited and, after 85 min, has ceased altogether. In all, after 4 years serially sub-culturing of all these organisms, for 360 passages, no insensitive strain of any strain has emerged.

## RADIOBIOLOGY

### Proteases and the Depletion and Restoration of Skin Responsiveness to Radiation

THE intravenous injection of a vital dye (pontamine sky blue, 1.2 ml. of 5 per cent solution/kg body-weight) immediately after local irradiation of a rabbit's skin (1,000 r., 60-140 kV) is followed within a few minutes by an intense blueing of the irradiated area, allowing the investigation of tissue events hitherto unnoticed in the so-called latent period. This circumscribed leakage of dye in the early phase of inflammation is abolished if the animals are pretreated with total or partial body irradiation (400 r., 230 kV, half-value layer = 1.8 mm Cu) or systemically with alkylating agents, and also with softer radiations used in order to avoid effects on deep-seated organs. This unresponsiveness is temporary, as the restoration of local reactivity occurs within six days in the experimental conditions described<sup>1</sup>.

In a further series of experiments with partial body irradiation and exposure of varying sizes of area in the pretreatment, it was shown that the abolition or reduction of tissue response is proportional to the extent of the pretreated area and that distant and local factors are involved in the degree of tissue responsiveness<sup>2</sup>.

These observations have a two-fold clinical importance. First, they indicate the possibility of achieving a potentiation of radiation effects, a form of radiosensitization, by fractionation in time in which the periods of reduced responsiveness to radiation are taken into account or by fractionation in space (sieve method) in which volumes of tissues protected from radiation afford anchorage and starting points for the complex phenomena that make up the radiation-induced inflammation. Secondly, they indicate that in grafting work, apart from the preliminary total body irradiation, local irradiation of the graft area at intervals of time dictated by the dose used in the pretreatment may prove advantageous regarding the rejection of grafted tissues.

Measurements with the technique of Grant and Rothschild<sup>3</sup> as modified by Miles and Niven<sup>4</sup> showed that the observed changes in vascular permeability were not related to a fall in blood pressure after total body irradiation.

The lack of response to local irradiation after total body irradiation appeared instead to be correlated with the number of circulating leucocytes, as an investigation of these in peripheral blood showed that the reappearance of the response coincided with the return of the number of leucocytes to their original level. An analogy could therefore be drawn with the observations made by Humphrey<sup>5</sup> and Pepys<sup>6</sup> on the role of leucocytes in the variation of the Arthus phenomenon and the abolition of the Mantoux reaction caused by alkylating agents.

While it is accepted that the very early changes in vascular permeability are mediated by histamine<sup>7</sup>, the delayed response, the subject of the experimental work here described, is independent of the histamine effect. Antihistamines, such as mepyramine and triprolidine, do not affect the delayed permeability response to local X-rays. Also 5-hydroxytryptamine (in the rabbit present in very small amounts only) has been proved not to play a part in these phenomena; its antagonist, lysergic acid diethylamide, has no effect on the degree of leakage of dye.

Further investigations have shown that soya bean trypsin inhibitor has an effect similar to that of total body irradiation. The results indicate that enzymatic processes are involved in the described phenomena of reduction or abolition and restoration of tissue responsiveness. This was confirmed in a series of experiments by the use of amino-*n*-caproic acid as the proteolytic agent. The action of this amino-acid in diminishing the capillary permeability supports the suggestion that this phase of inflammation is initiated by a protease system liberating proteolytic portions pharmacologically active on capillary endothelium.

However, the influence of the structure of these macromolecules has also to be considered, as was shown in another series of animals by the marked effect on the first phase of inflammation of meso-inositol hexanicotinate ('Hexopal', Bayer-Winthrop, Ltd.). It was similar to the effect of meso-inositol used by Brinkman<sup>8</sup> in his investigations of substances with radioprotective or radiosensitizing properties.

Without elaborating too much it can be stated that the reactions observed are due to an interplay or balance between permeability factors and their inhibiting enzymes. It is possible that the pretreatment at first depletes the amount of inhibiting enzyme and hence gives free way to the permeability-increasing factor until the inhibiting enzyme is restored (24-36 h) or the promoting enzyme is depleted.

There may be also an increase of pharmacologically active poly- or oligo-peptides due to tissue demolition products or the acid-alkaline phases in blood and tissue following irradiation, and these may influence the enzymatic balance, as it is accepted that acidosis in itself enhances capillary permeability and thus plays a part in inflammation.

This work was supported by a grant from the British Empire Cancer Campaign for Research.

## BIOLOGY

### Diagrams of Changes in the Distribution of Plant Dry Weight or Other Variables

IN investigations of plant development it is helpful to be able to represent diagrammatically the changes which occur in the distribution of dry weight, total nitrogen or some other variable as the plant grows. It is usually desirable to distinguish at least four components of the plants of different physiological function, namely, leaf laminae, stems plus petioles, flowers plus fruits and roots, though data for the last-mentioned are often lacking. The values of the variable for each of these components should be plotted against a suitable independent variate which may be, for example, age, node number, leaf area or total dry weight. If the variable for the four components is plotted as four ordinary two-dimensional graphs, whether independently from the same base line or superimposed to build up the total, it is not easy to see whether the ratios of the values for the different components are constant or changing with growth of the plant. This can be seen by plotting logarithms of the values of the variable, but then their absolute magnitudes are obscured.

These difficulties have been partly circumvented by developing a substitute for a five-dimensional diagram. An example is shown in Fig. 1, which represents the distribution of dry weight in the barley plant during the second half of the growth cycle when ear development takes place (data for season 1938 from ref. 1). To plot such a diagram triangular graph paper ('isometric grid') is used and one of the three axes is selected for the independent variate (marked 'days from sowing' in Fig. 1). At any point on this axis a vertical line downwards gives the value of the variable for roots ( $R$ ), a vertical line upwards for flowers plus fruits ( $F$ ), a line to the right for leaves ( $L$ ) and one to the left for stems plus petioles and seedlings ( $S$ ). In the example chosen for Fig. 1 there are, of course, no petioles and the leaf sheaths have been included with 'stems'.

The ends of the lines for roots, leaves, flowers and stems may be joined to give four triangles. If the partition of dry weight has not changed with growth of the plant, the corresponding triangles will be similar and the corresponding lines all parallel. Changes in ratio of dry weights for  $R:S$ ,  $R:L$ ,  $L:F$  and  $S:F$  can be readily seen from the changes in shape of the appropriate triangles. It is a weakness of the diagram that this type of comparison is only available for four of the six possible ratios, which depend on the directions chosen for plotting the variable or the four components, and in Fig. 1 the changes in ratio of dry weight for  $L:S$  and  $F:R$  are not so easily seen. To assist in these last comparisons the  $L$  dry weight may be marked off on the  $S$  line and the  $F$  dry weight on the  $R$  line by short strokes (Fig. 1).

As an alternative to drawing the triangles the parallelograms may be completed, as has been done for one occasion (81 days) in Fig. 1. The changes in their shapes then indicate the changes in ratios. This method has the

Fig. 1

advantage that it also indicates changes in  $R:(L+S)$ ,  $F:(L+S)$ ,  $L:(F+R)$ ,  $S:(F+R)$  and  $(F+R):(L+S)$ .

If desired the successive values of each component may be joined to emphasize the relations with the independent variate, and an example of this may be seen in ref. 2.

### Ion Uptake and Protein Synthesis in Enzymatically Isolated Plant Cells

THE D-threo isomer of chloramphenicol is an antibiotic and a specific inhibitor of protein synthesis in bacteria<sup>1</sup>. It also inhibits protein synthesis (net synthesis or turnover) in higher plants<sup>2-6</sup>, including cell-free systems<sup>7,8</sup>. Suppression of the induced increase in oxygen uptake in potato disks by D-chloramphenicol<sup>9</sup> has been considered as indirect evidence of an inhibition of protein (possibly cytochrome oxidase) synthesis. Enzyme development during germination was also inhibited by D-chloramphenicol<sup>10,11</sup>. Recently, this chemical has also been used in several systems to relate ion uptake to protein synthesis in higher plants<sup>2,3,6,12-16</sup>. Others oppose this interpretation<sup>17-20</sup>. Meanwhile, the extrapolation of information on chloramphenicol from bacteria to higher plant systems has been criticized<sup>4,18</sup>. Ellis<sup>18</sup>, for example, observed that D-chloramphenicol did not affect incorporation of amino-acids into protein (trichloroacetic acid (TCA)-insoluble fraction) and yet it reduced ion uptake in higher plants. In contrast, the L-threo-isomer of chloramphenicol, which is neither an antibiotic nor an inhibitor of protein synthesis in bacterial systems, does inhibit ion uptake<sup>18</sup> and root growth<sup>21</sup> in higher plants. Thus, further elucidation was necessary as to the action of chloramphenicol as an inhibitor of ion uptake via an effect on protein synthesis.

The comparative effects of the D- and L-threo isomers of chloramphenicol on rubidium uptake and protein synthesis were determined on a mixture of palisade and

mesophyll cells enzymatically isolated from partially expanded, green tobacco leaves (*Nicotiana tabacum* L. Burley type). Cell separation procedures were modified after Zaitlin<sup>23</sup>. The separation mixture contained pectinase 0.2 per cent, peptone 0.2 per cent, glycerol 2 per cent, sucrose 0.1 M, ethylenediamine tetraacetic acid (EDTA) (pH 6.4) 0.02 M, *tris*(*tris*-(hydroxymethyl)amino methane) maleate (pH 6.4) 0.02 M, K<sub>3</sub>-citrate 0.01 M and Na<sub>2</sub>-succinate 0.01 M. Isolated cells were washed with cold 0.35 M sucrose containing 0.0002 M CaCl<sub>2</sub>, and suspended in ice-cold 0.35 M sucrose until utilized. Isolated cells retained only 25 per cent of protein (TCA-insoluble fraction) originally found in the leaf lamina of comparable weight. Further details of the methods for separating leaf cells and mechanisms of ion uptake by these cells will be published elsewhere<sup>23</sup>.

Investigations of the uptake of rubidium proceeded as the cells were suspended in solutions in 125-ml. Erlenmeyer flasks in a water-bath shaker in the light (about 500 ft.-candles) and at 25 ± 1° C. Each flask contained the following in 15 ml.: living cells equivalent to 133 mg dry wt., sucrose 1.76 mmoles, Na<sub>2</sub>-succinate 30 μmoles, NaHCO<sub>3</sub> 30 μmoles, MgCl<sub>2</sub> 1.5 μmoles, peptone 3 mg, casein hydrolysate 0.1 per cent, *tris*-maleate (pH 6.4) 150 μmoles, and 250 p.p.m. chloramphenicol as a variable. Cells were pre-incubated for 11 h in the aforementioned solution before the introduction of 0.5 μc. <sup>86</sup>Rb/1.5 μmole RbCl plus 'Tween-20' (polyoxyethylene (20) sorbitan monolaurate, final conc. 0.01 per cent). Treatments were duplicated, and the absorption period was 12 h. Cells in 1-ml. portions of incubation mixture were collected on filter paper (2.1 cm diam.), with mild suction, and washed with 1 ml. of 0.35 M sucrose. Air-dried samples were used for radio-assay.

Similar experimental conditions and procedures were utilized in investigations of the absorption of glycine-1-<sup>14</sup>C and its incorporation into the protein of suspended leaf cells. Each flask contained the following in 7.5 ml.: living cells equivalent to 50 mg dry wt., sucrose 880 μmoles, glycine-1-<sup>14</sup>C 1 μc. (specific activity of 249 μc./μm), casein hydrolysate at 0.1 per cent, peptone 1.5 mg, Na<sub>2</sub>-succinate 15 μmoles, NaHCO<sub>3</sub> 15 μmoles, MgCl<sub>2</sub> 0.75 μmoles, *tris*-maleate (pH 6.4) 75 μmoles, and 'Tween-20' at 0.01 per cent. At the end of an experiment the incubation mixtures were quantitatively transferred to centrifuge tubes. Cells were spun down by centrifugation, and supernatants discarded. They were then washed by resuspension and centrifugation with 5 ml. of 0.35 M sucrose. Cell pellets thus obtained were resuspended in 15 ml. of 70 per cent ethanol. Incorporation of glycine-1-<sup>14</sup>C into protein was ascertained by counting the radioactivity remaining in the alcohol insoluble fraction after 8 h extraction. This alcohol insoluble fraction has been designated as protein<sup>24-27</sup>. Total absorption of glycine was expressed as the sum of radioactivity recovered in the alcohol soluble and insoluble fractions.

Absorption of rubidium was significantly reduced by both D- and L-threo isomers of chloramphenicol (Table 1). The L-isomer was 77 per cent as effective as the D-isomer.

Similarly, both isomers of chloramphenicol inhibited the incorporation of glycine into protein (Table 2), with the D-isomer correspondingly more effective than the L-isomer. There were no significant differences in the radioactivities recovered in the alcohol soluble fractions. The activities were 134, 144 and 129 c.p.m. for the control, D-chloramphenicol, and L-chloramphenicol treatments, respectively. This suggests that the primary

Table 2. EFFECTS OF D- AND L-THREO ISOMERS OF CHLORAMPHENICOL (250 P.P.M.) ON GLYCINE-1-<sup>14</sup>C UPTAKE, AND ITS INCORPORATION INTO THE PROTEIN OF CELLS ISOLATED FROM GREEN TOBACCO LEAVES

Treatment	Glycine uptake (c.p.m./12 h)	Glycine incorporation (%) <sup>a</sup>	% Reduction of incorporation
Control (no treatment)	197	32.1	—

L-Chloramphenicol	155	10.6	48.3

<sup>a</sup> Represents that percentage of total glycine absorbed.

effect of chloramphenicol was on protein synthesis, and not on amino-acid uptake.

The parallel inhibition by the D- and L-chloramphenicol isomers of uptake of rubidium and incorporation of glycine into protein suggests that absorption of rubidium is closely correlated with protein synthesis. The isolation and identification of a particular protein associated with uptake of rubidium remain to be elucidated.

This is report C00-888-38 in co-operation with the Division of Biology and Medicine of the U.S. Atomic Energy Commission, contract At-(11-1)-888. The D- and L-threo isomers of chloramphenicol were provided by Parke, Davis and Co., Detroit, Michigan.

### Precision of Thermocouple Psychrometers for measuring Leaf Water Potential

INCREASING use is being made of psychrometric methods of measuring vapour pressure in biological systems as a means of assessing the energy status of water in the system, using a small thermocouple as a psychrometer to measure relative humidity under constant temperature. The choice of equipment is obviously related to the use to which it is to be put, but for laboratory estimates of soil water potential the simplest equipment described to date is that of Monteith and Owen<sup>1</sup>. This method has been modified, by greatly reducing the size of both thermocouple and chamber, to ensure the rapid equilibration needed with plant tissue samples, and has then been used for making an assessment of the precision of measurements of leaf water potentials. Full details of the equipment used are given elsewhere<sup>2</sup>.

In testing precision the interest lies in the relation between measuring and sampling errors, and in the sources

Table 1. EFFECTS OF THE D- AND L-THREO ISOMERS OF CHLORAMPHENICOL (250 P.P.M.) ON UPTAKE OF RUBIDIUM BY CELLS ISOLATED FROM GREEN TOBACCO LEAVES

Treatment	Rb uptake (μmole/mg dry wt. × 12 h)	Per cent inhibition
Control (no treatment)	0.42	—
D-Chloramphenicol	0.07	83
L-Chloramphenicol	0.15	64

f these errors. The equipment is calibrated against sodium chloride solutions of known molality, which give known vapour pressures at 25° C, and the precision with which relative humidity can be measured in the chambers is shown by the variation between measurements made with standard NaCl solutions. The assessment of error involved in measurement of leaf water potential is complicated by the fact that large numbers of leaves known to have the same water potential are not available, as it has been found that leaf water potentials may vary within a plant according to the position of leaves on the stem. For estimates of this error it therefore seemed advisable to regard only the two halves of a symmetrical leaf, lying on either side of the midrib, as having potentially identical water status. Estimates of precision were therefore based on an investigation of such paired samples.

Four pairs of thermocouples were used and the same pairings maintained for all determinations. Osmotic potentials were estimated on the same leaf samples, following snap freezing with solid carbon dioxide to release cell sap<sup>3</sup>. The species used was *Salvia patens*, originally elected for its convenience in making measurements of leaf expansion over short intervals of time. Twenty-four fully expanded leaves were used from plants that had been subjected to varying degrees of water strain (by allowing the soil to dry out), and two samples from each leaf were examined in turn for leaf water and osmotic potentials. Finally, measurements were made on NaCl solutions of 0.1 M, 0.2 M, and 0.3 M molality, covering approximately the same range of potentials as the leaf tissue determinations. Two samples of each solution were used with every thermocouple, giving a total of 48 determinations, as with the plant material.

Table 1. STANDARD ERROR OF DETERMINATIONS OF POTENTIALS (Metres of water)

Determination	Mean potential of each series	Range of potentials in the series	Within-chamber error	Sampling error
Water potential of tissue	-66.0	-23 to -127	±0.66	±2.51
Osmotic potential of tissue after freezing	-99.0	-60 to -118	±0.80	±1.71
Potential of salt solution	-94.0	-47 to -141	±0.90	±0.91

In order to assess the main sources of error, it was necessary to examine the variation between (a) successive determinations on a particular sample and (b) simultaneous determinations on twin samples taken from the same leaf or from the same stock solution of NaCl. Readings were taken 4 and 5 h after the samples were taken, by which time the system was at vapour equilibrium<sup>2</sup>, and the mean of these two readings was used in calculating standard errors for each series of determinations, that is, for the water potentials of tissue and salt solutions and the osmotic potentials of killed tissue respectively. The standard error of the mean of two successive readings taken for each individual sample can be regarded as 'within-chamber' error (Table 1), while the standard error of the mean of the pair of tissue samples for each leaf is the sampling error. Comparable values derived in the same way have been calculated for the determinations of osmotic potentials and salt solution potentials.

Within-chamber error for salt solutions, due mainly to limitations in temperature control, circuitry, and/or vapour leaks, was relatively small. The within-chamber error for leaf water potential is always likely to be greater than this, since it includes variations due to physiological activity of the tissue between the 4th and 5th h, but this effect was apparently small since the standard error was similar to that of the salt solution. Similarly, errors due to changes in osmotic potential between the 4th and 5th hours were unimportant. The sampling error for paired samples of salt solutions includes the variation introduced by handling the thermocouples and chambers in the preparation of each sample. Possible sources of error include contamination of the couples during exposure to the room atmosphere, inequalities of pressure between paired chambers arising during insertion

of the bungs (though precautions were taken to prevent these), and differing positions of the thermocouples relative to the evaporating surfaces. The measured error ( $\pm 0.91$  m) was much smaller than those associated with plant tissue samples ( $\pm 2.51$  and  $\pm 1.71$  m for water potentials and osmotic potentials respectively). It was therefore concluded that temperature control, circuitry and technique were adequate for the measurement of water and osmotic potentials of leaf tissue within the limits of accuracy imposed by sampling. The range of leaf water potentials which is of interest in irrigation research is that between full turgor and first signs of wilting, by which stage it is generally accepted that growth has been seriously affected. In *Salvia* this range extended from zero to about -100 m of water, and the method proved amply sensitive to cover the whole of this range, with a degree of accuracy that makes it a useful technique for agronomic work concerned with the water relations of plants grown under a variety of soil conditions.

### The Bank Vole, *Clethrionomys glareolus* Schreber: a Mammal New to Ireland

ON August 20, 1964, one of us (A. J. M. C.), while trapping for small mammals near Listowel, County Kerry, caught an unusual 'mouse'. On subsequent examination it proved to be a member of the family Cricetidae, the bank vole, *Clethrionomys glareolus* Schreber—a family of mammals hitherto unknown from Ireland<sup>1-4</sup>.

The same area was again trapped during August 28-30 and a further 16 specimens were taken consisting of seven adult and three immature males, one immature and five adult females, in both breakback and Longworth live traps. These were all bank voles and were actively reproducing. Of the specimens caught by breakback traps, one female had three obvious foetuses (C.R. length 11 mm) *in utero*, and sperm production was evident in three of the males killed. The smallest animal (a male) weighed 11.2 g. Trapping was carried out in bramble and bracken banks and in dense grass and herb layers.

The density and ease of trapping of this species in this area is high: during the first 12 h (overnight) of trapping, one vole was caught per 3.83 traps. As the traps were not moved, this level dropped during the following 12 h (daylight) to one vole in 10.2 traps, excluding a *Mus musculus* (L.) caught during this period, and in the third 12 h (again overnight) only one vole was caught (1 per 36 traps). During this, the final trapping period, 4 *Apodemus sylvaticus* (L.), 1 *Mus musculus* and 1 *Sorex minutus* (L.) were also caught.

The replacement of the voles in this area, which was less than 1 acre in extent, might suggest that they are in active competition with these other species, especially *Apodemus*. However, despite this apparent competition it is more probable that *Clethrionomys* and *Apodemus* are not in active competition due to different activity cycles: *Apodemus* being essentially crepuscular and *Clethrionomys* diurnal, and because of the preference of voles for denser cover. Until extensive grid trapping is carried out it will be impossible to say with any certainty the habitat requirements of *Clethrionomys vis-à-vis Apodemus* in Ireland.

Preliminary examination of the skull suggests that the specimens are virtually identical with the British mainland and continental forms. A fourth inner loop is found on the third upper molar in some bank voles, which is regarded as a complex condition. This complexity occurs in 16 per cent of southern English bank voles, 33-41 per

cent in northern England and Scottish specimens, while Hebridean Island specimens show the complexity in c. 80 per cent of the cases<sup>4</sup>. Out of all the skulls examined (nine) in the present series, only one (11.1 per cent) showed the dental complexity of *M*<sup>3</sup>.

Comparisons of cranial characters were made with series of British mainland and continental specimens, by Dr. G. B. Corbet in the British Museum (Natural History). The characters compared were hind foot, condylo-basal length, zygomatic width, cranial width, interorbital width, anterior palatal foramina, length of maxillary tooth-row, relative lengths of *M*<sup>1</sup>, *M*<sup>2</sup> and *M*<sup>3</sup>, fourth inner loop of *M*<sup>3</sup>, length of nasals and width across condyles. The only detectable difference is that the nasals are on average shorter and the condyle width greater than British forms, but even here there is considerable overlap. From the evidence at present available it would appear that this Irish population is essentially similar to that in England. Trapping in neighbouring counties suggests that this population is restricted in distribution. Investigations now being carried out are aimed at establishing the present distribution of this species in Ireland.

We thank Dr. G. B. Corbet for making comparisons between the specimens and those in the British Museum (Natural History).

*Note added in proof.* Further specimens have recently been obtained from Co. Limerick, 50 miles from Listowel.

### Environmental Acclimation in the Limpet *Patella vulgata* L.

THE differences in intertidal distribution of the two British species of prosobranch limpets *Patella vulgata* L. and *P. aspera* Lamarck have been well documented. *P. aspera* is limited to low shore-levels on shores exposed to wave action, while *P. vulgata* is widely distributed between high and low water levels on both exposed and sheltered shores<sup>1,2</sup>. During my investigation into the reasons for the differences in their distribution in the Clyde Sea area it was found that populations of *P. vulgata* from high shore-levels display physiological differences in several ecologically important characters when compared with those living at low shore-levels. Differences were observed in metabolic rate, the rate of loss of water under desiccating conditions and the ability to withstand loss of body water.

Metabolic rate, determined as the rate of respiration of whole animals in air, was used as an indicator of "internal physiological state" of the animals. Respiration was measured by means of a new type of constant pressure respirometer<sup>3</sup> and expressed as cubic mm of oxygen consumed/g wet weight soft parts/h. It was found that in summer the rate of respiration of high-level limpets is significantly lower than that of low-level limpets at temperatures of both 5°C and 15°C (Fig. 1). These differences in rate of respiration are not found during the winter months but reappear during the spring as the respiration rate of the low-level limpets begins to increase again. The respiration rate of the high-water limpets remains almost constant throughout the year.

Fig. 1. Respiration rate of high-shore level ( $\Delta$ ,  $\blacktriangle$ ) and low-level ( $\circ$ ,  $\bullet$ ) *Patella vulgata* at 5°C and 15°C in July 1962. Regression lines are fitted by the method of least squares

For certain Californian molluscs, thermal acclimation has been postulated to explain differences in the rate of pumping of the gills in *Mytilus californianus*<sup>4</sup> and rate of heart beat of *Acmaea limatula*<sup>5</sup>, correlated with differences in tide level. In *Patella*, present results suggest that intake of food is also a causative factor, since in another series of experiments it was found that of all limpet populations on the seashore, the highest respiratory rate was recorded from those living beneath a cover of fucoid seaweeds and the lowest from a population living on rocks covered with barnacles. Reciprocal transplantation experiments demonstrated that these differences did not result from genetic selection, since after two months high-level limpets transplanted to low-level habitats had a higher respiratory rate than low-level animals which had been transplanted to high levels.

Under desiccating conditions similar to those experienced by the animals on the seashore when uncovered by the tide, it was found that the rate at which water is lost is related to the size of the limpets. In low-level limpets loss of water is proportional to the power  $-0.41$  of the body-weight, and in limpets from high water-levels, to the power  $-0.55$  of the weight. When compared at the same weight, low-level limpets lose water at a higher rate than high-level ones. In addition, there are differences in tolerance of loss of water during desiccation. In a sample of low-level limpets, 50 per cent succumbed to a loss of water of 50 per cent of their body weight while 50 per cent of a sample of high-level limpets were able to withstand a loss of water of 60-65 per cent of their body-weight.

It is clearly advantageous to limpets living under the adverse environmental conditions prevailing at high levels on the shore to maintain a lower metabolic rate, withstand greater losses of water and to lose water more slowly than those living at low shore-levels. Evidence is accumulating that ability to acclimate to wide ranges within the environment is of prime importance in the wide intertidal distribution of *P. vulgata*. From other studies, not detailed in this communication, it appears that this ability is not well developed in *P. aspera*.

This work was carried out during the tenure of a Department of Scientific and Industrial Research research studentship, and I thank Dr. C. H. Mortimer and Prof. C. M. Yonge for the provision of research facilities.

## Peritrophic Membranes in the Phalangida

PERITROPHIC membranes have not been recorded in the Achnida although they are a widespread, but not universal, occurrence in insects. Phillipson<sup>1</sup> noted the occurrence of 'lamellated membranes' in the hind-gut region of *Itopus morio* and also in *Opilio*, *Platybunus*, and *Igolphus agrestis*, which he suggested were the source of the membrane of the faecal pellet. The purpose of the present communication is to record the presence of a peritrophic membrane in nymphal oligolophids and adult *Obunum rotundum* Lat. and *Phalangium opilio* Linn. though absent from the mid-gut diverticula it extends throughout the lumen of the alimentary canal and is composed of a series of concentric lamellae. It is therefore comparable with one of the two principal types found in insects.

After sectioning at 7 $\mu$ , measurement of the lamellae in photographs, at a magnification of  $\times 3,000$ , showed that each one was c. 0.5 $\mu$  in thickness. They were often situated close to the gut epithelium, are almost certainly homologous with the membrane of the faecal pellet noted by Phillipson<sup>1</sup>, and provided an interesting comparison with the membranes of insects. More detailed investigations are in preparation.

## ENTOMOLOGY

## Batelli Glands of Cercopoid Nymphs (Homoptera)

Two major groups of theories have been proposed during the past 60 years or so to account for the formation of 'spittle' or foam by cercopoid nymphs. On one hand, the site of origin of the compound stabilizing the bubbles of foam is attributed to the glands of Batelli<sup>1-6</sup>, and the other to the Malpighian tubules<sup>7-10</sup>.

The Batelli glands have, from time to time, been supposed to produce a 'mucilaginous' compound<sup>2,5</sup> or a component or components of a 'soap'<sup>3,6</sup>. Such compounds, it is suggested, behave as surface tension depressants.

Batelli glands are swollen hypodermal glands, the precise location of which has been variously described. Batelli<sup>11</sup>, who first figured these glands, considered them to be on the last two abdominal segments. Gruner<sup>12</sup> and Porta<sup>13</sup> located them on the 7th and 8th abdominal segments, while Berlese<sup>1</sup> placed them on the 8th and 9th abdominal segments.

In the species of the family Cercopidae which I have examined, Batelli glands do not always appear to be present (Table 1). When present they are readily seen as ventro-lateral swellings on the 7th and 8th abdominal segments. The presence of 'wax plates', usually present ventrally at these sites, further facilitates identification. Although ventro-lateral swellings are not so readily discernible in adults, the presence of 'wax plates' in some adults serves to confirm the functional existence of the glands. As noted by Guilbeau<sup>2</sup>, setae appear to be absent from the cuticle in these regions.

In the species of the family Machaerotidae examined, Batelli glands are present on the 6th, 7th and 8th abdominal segments of nymphs of *Pectinariophyes stali* Grunberg and *Machaerota coronata* Maa. Maki<sup>14</sup> found Batelli glands on the 7th and 8th abdominal segments of nymphs of *Makiptyelus dimorphus* Maki; this observation was confirmed. Batelli glands also occur on the 7th and 8th abdominal segments of nymphs of *Chaetophyes compacta* Ulker. In these latter two species, however, the 6th

Table 1. PRESENCE OR ABSENCE OF BATELLI GLANDS IN CERCOPOID SPECIES

Species	Observed externally		Observed in sections	
	Nymph	Adult	Nymph	Adult
Sub-family cercopinae

<i>Philaenus leucophthalmus spumarius</i> Linnaeus	+	+	+	
<i>Psophitus</i> sp.	+		+	
<i>Ptyelus</i> sp.	+		+	
<i>Bathylus albicinctus</i> Erichson	+	+	+	
<i>Clovina lineatocollis</i> de Motschulsky	+		+	

0, absent; +, present.

abdominal segment is modified ventrally to form part of an abdominal operculum.

The absence of Batelli glands in two species of the family Cercopidae suggests that these glands are not involved in the production of a bubble stabilizing agent in 'spittle'. This conclusion is supported by the presence of three pairs of glands in some nymphs of the family Machaerotidae, since the latter nymphs have very limited spittle-producing requirements and produce 'spittle' only at the times of ecdyses<sup>15</sup>.

It is of some interest that in the Cercopidae the two species lacking Batelli glands belong to the sub-family Cercopinae; the members of this sub-family are subterranean and produce 'spittle' masses on plant roots<sup>16</sup>. It has been suggested that the subterranean habit is a primitive adaptation to arid conditions<sup>17,18</sup>. Now Sule<sup>3</sup> and Gahan<sup>5</sup> both considered the secretion of the Batelli glands to be a wax, and Kato<sup>8</sup> detected a lipid which stains with sudan black B in these glands, an observation which I have confirmed (unpublished). Thus there seems little doubt that the Batelli glands produce a lipid substance which is possibly a wax. The production of such a substance may therefore be associated with the prevention of desiccation in above-ground dwelling cercopoid nymphs.

Biochemical Changes in *Semiadalia undecimnotata* (Schneider) Adults during Diapause

THE function of food reserves during diapause is often discussed, but there are very few reliable data. The mass hibernation of adult *Semiadalia undecimnotata* (Schneider) (Coccinellidae) in accessible places allowed us to make analyses throughout the winter. Both sexes arrive at the winter quarters on warm, windless days from the end of July to the end of August, and leave from the end of April to the end of May, according to the temperature.

Samples were taken during three aestivo-hibernating seasons in the years 1957-59 in the Louny Hills in Northern Bohemia. Dry matter, glycogen and fat were determined<sup>1</sup>.

The absolute water content fluctuated considerably, from 6.8 to 13.5 mg in males, and from 7.9 to 16.2 mg

in females. During the eight-month period there was no general trend in either sex. The changes in water content may be attributed partly to the active uptake of water from the environment and partly to the production of metabolic water through fat metabolism. It seems probable that the Coccinellids drink water after their body water content has decreased during dry periods. The gradual increase in the relative water content is caused by the fall in weight of dry matter. In males the absolute water content is lower but the proportion of water is higher than in females.

Fat reserves are accumulated before migration. The digestive tract of both sexes is empty when they arrive at the winter quarters, and they do not feed until after they leave. A decrease in fat content during aestivo-hibernation is therefore to be expected, and was observed in all three seasons. At the beginning of the diapause (August 29, 1958) the fat content was as high as 6.4 mg in the males and 7.2 mg in the females, and this fell to minimum values of 1.2 and 1.7 mg in the males and females, respectively, at the end of aestivo-hibernation (May 9, 1959). Undoubtedly the actual decrease was even greater because the first sample for analysis was taken about one month after the Coccinellids had arrived at the winter quarters. The results (Table 1) show that the fat reserves are important as a source of energy during migration to the winter quarters and also during aestivo-hibernation. The ripening of ovaries in spring begins only after the Coccinellids have begun feeding.

The rate of decrease in fat reserves evidently depends on the outdoor temperature, which affects the activity and the metabolic rate of the insect (Table 1). The fall is very steep in the initial warm phase of aestivo-hibernation, whereas in the cold phase (November–March) there is only negligible daily decrease. The warmer spring weather increases the rate of fat metabolism during April and at the beginning of May.

The fat contents of the insects taken on similar dates in different years were similar. It is surprising that the trend of decrease in the fat reserves is essentially similar in both sexes despite substantial differences in the condition of their gonads. The female ovaries are in a state of undifferentiated germaria throughout diapause. In contrast the testicular follicles of the males show active meiosis except during the coldest period of hibernation<sup>2</sup>. Apparently the activity of testes requires relatively little energy and therefore does not make significant demands on the fat reserves. A similar situation has been described in *Pyrhocoris apterus* L.<sup>3</sup>.

The absolute as well as relative content of glycogen fluctuated considerably throughout aestivo-hibernation, although there was a general decrease. The highest absolute values were recorded at the beginning of the diapause, 388 and 432 $\gamma$  in the males and females, respectively (August 29, 1958), the lowest at the end

of the diapause, 94 $\gamma$  in the males (April 23, 1957) and 71 $\gamma$  in the females (May 13, 1958). Females always had more. In spite of many irregularities it can be seen (Table 2) that the environmental temperature affects the rate of decrease of glycogen. The amount of glycogen fluctuated much less than the glycogen reserves in samples taken at any one time as well as at different times.

A comparison of our results with data on other insect species shows that *S. undecimnotata* has the highest fat content of any so far described, whereas the glycogen content, compared with rather contradictory and inadequate data from other insects, seems to be relatively very low.

### Multiplicity of Neurosecretory Cell Types and Groups in the Brain of the Saturniid Moth *Hyalophora cecropia* (L.)

As part of an extensive investigation of the anatomy and histology of the known endocrine organs of *Hyalophora cecropia* in the last 2 larval stages and in pupae and adults, we have examined the brain neurosecretor (NS) cells utilizing paraffin sections and the standard N stains, paraldehyde-fuchsin (PAF) with counterstains an chrome-haematoxylin (CH) with phloxine. Previous workers<sup>1,2</sup> had reported the existence of 26 apparently identical NS cells in the brain of this insect. Our results demonstrate the presence of at least 40 such cells and provide histological evidence for the occurrence of several distinct functional types.

The problems involved in correctly identifying NS cells are complex<sup>3</sup>. We have defined such cells in this animal as neurones which undergo alterations in their content of prominent stainable inclusions and which exhibit cytological evidence of axonal transport of the stainable materials to the corpora cardiaca. All the cell types discussed below fulfil these criteria.

Putative NS cells occur in 3 locations in the pars intercerebralis (PI) of the protocerebrum of this moth. They form the 2 major groups characteristic of insects (the pair medial and lateral nuclei) and also form a third pair clusters in the posterior PI. Eleven cells of 4 distinguishable types occur in each medial cluster, whereas the lateral nuclei each contain 7 cells of 2 distinct types. The posterior nuclei are each composed of 2 cells of a single type. Fig. 1 is a representation of the locations of the various cells and Table 1 lists their dimensions.

The NS cells of this insect fall into 2 major categories. One category, designated as 'A' cells, is characterized by cytoplasmic inclusions staining shades of purple with PAF and blue-black with CH. The inclusions of the second category of cells, the 'B' cells, usually stain shades green with the PAF counterstains and reddish with phloxine. The cells of each major category can be divided into sub-categories on the basis of size, location and number. In addition, each sub-category is characterized by periods of accumulation and depletion which are not identical to those occurring in cells of any other sub-category. Although the exact implications of these fluctuations are not as yet fully understood, they are interpreted as variations in the functional activity of the cells involved.

(1) The 'A' cells.

(a) The large medial 'A' cells. Cells of this type are the largest 'A' cells of the medial cluster in the larva

Fig. 1. A diagrammatic representation of the locations of the various types of neurosecretory cells in the brain of *Hyalophora cecropia*.

ages. Their inclusions are small and, in larval stages, are prominent than those of the small medial 'A' cells. These cells exhibit minor alterations in their content of inclusions in larval stages and major alterations in older animals. Four cells of this type can be readily distinguished in each medial cluster in larvae and young pupae; in older pupae and adults they are similar to the small medial 'A' cells and are less readily identifiable.

(b) The small medial 'A' cells. Four cells of this type are easily recognized in each medial cluster of larvae and young pupae where their inclusions are larger and more deeply stained than those of the large medial 'A' cells. Prominent variations in the number of inclusions in these cells occur only in pupae and adults.

(c) The deep medial 'A' cells. Two of these cells are conspicuous in the ventral region of each medial nucleus during the pupal and adult stages, but these cells cannot be easily identified in larvae. In adults they are frequently the largest of the several types of 'A' cells. They only maintain prominent inclusions in young pupae.

(d) The posterior 'A' cells. As with the deep medials, these cells are not conspicuous in most larval stages. In the fifth instar larvae and older animals they usually maintain prominent inclusions.

(e) The lateral 'A' cells. Five of these cells form a cluster on or near the dorsal surface of the neuropile. Typically the smallest of the 'A' cells, and possessing the smallest nuclei, they are devoid of inclusions during portions of each stage investigated.

## (2) The 'B' cells.

(a) The medial 'B' cells. One cell of this type lies in the dorsal region of each medial cluster. These cells exhibit fluctuations in their content of inclusions during each stage of the life-cycle, but such variations are most prominent in pupae and adults.

(b) The lateral 'B' cells. Two cells of this type lie at a short distance lateral and dorsal to the lateral 'A' cells. Unlike the medial 'B' cells, they contain both 'A' and 'B' type inclusions late in each larval stage. Like the medial 'B' cells their alterations are most prominent in later developmental stages.

Table 1. MAJOR DIAMETERS ( $\mu$ ) OF BRAIN NS CELLS AND THEIR NUCLEI IN *H. cecropia*

	Cells	Nuclei
'A' cells		
Large medials	25-40	10-13
Small medials	15-25	7-10
Deep medials	25-45	10-15
Posteriors	20-30	10-13
Laterals	15-25	6-9
'B' cells		
Medials	25-30	9-12
Laterals	20-25	8-11

The 'A' and 'B' cells are the only neurones in the brain of this species which meet the criteria for NS cells already mentioned here. Other large neurones are intermingled with the presumed NS cells, and such large neurones are also found in other regions of the brain cortex. In one 2-day-old developing adult a single cell was observed near one optic lobe which contained prominent 'A' type inclusions in both perikaryon and axon. The possibility therefore exists that other NS cells may occur in the brain of this moth.

Although the brain of *H. cecropia* has only been proved to produce a single hormone<sup>4</sup>, the occurrence of several apparently distinct NS cell types suggests that this brain may be the source of several hormones. Our findings are similar to those reported for other Lepidoptera<sup>5-10</sup> and appear to be duplicated in 2 other saturniids which we have investigated, *Antheraea polyphemus* and *Philosamia cynthia*. In particular, the posterior clusters appear likely to be characteristic of this order<sup>8-10</sup>.

The probability exists that the insect brain in general contains not only a multiplicity of NS cell types but also groups of NS cells located in other than the classical medial and lateral nuclei; support for this view has already emerged from investigations of representatives of such diverse orders as the Apterygota<sup>11</sup>, Dictyoptera<sup>12</sup> and Diptera<sup>13</sup>.

## MICROBIOLOGY

### Microscopic Picture of Reversion of Glycine Spheroplasts into Rods in *Escherichia coli*

In recent years much attention has been devoted to the reversion of spheroplasts into normal cellular forms of Gram-negative bacteria from both the biochemical and morphological points of view.

Until now—so far as we are aware—only Jeaynes<sup>1</sup> has observed the evolution of spheroplasts prepared under the influence of glycine ( $\alpha$ -aminoacetic acid). He described the reproduction of *Vibrio cholerae* spheroplasts and also mentioned their reversion into cellular forms while decreasing the glycine content in the medium gradually;

Fig. 1. Growth, division and regeneration of glycine spheroplasts of *Escherichia coli*: a, 1 h; b, 3 h; c, 4 h; d, 4.5 h; e, 5 h; f, 5.5 h; g, 6 h; h, 6.5 h; i, 8 h; j, 9 h ( $\times 750$ ).

he did not describe, however, through which morphological changes this reversion took place.

Our observations of the regeneration of glycine spheroplasts of *Escherichia coli* may be of some interest in this connexion. They were made in the course of control experiments when studying the morphological changes of the spheroplasts caused by colicin<sup>2</sup>.

We prepared spheroplasts from bacteria of strain I7 of *E. coli*<sup>3</sup> influenced by 3 per cent (w/v) glycine according to Jeynes<sup>4</sup>. Separated from the glycine medium and resuspended in broth, a drop of the suspension was placed on a low meat-peptone agar block on a slide, covered with a coverslip and framed by paraffin. These preparations were observed under a phase contrast microscope. Fixed fields of vision were photographed at different time limits<sup>4</sup>.

Part of the spheroplasts always lysed after having been transferred to the agar block; with the strain used in our case, however, the lysis did not exceed 20 per cent in the course of the first 3 h. About 50–90 per cent of spheroplasts grew and regenerated into rods. Growth of the majority of spheroplasts was conspicuously rapid—within the first hour—and regeneration of the rods began in 3 h.

Three kinds of regeneration were observed: (a) through a direct bipolar growth of the spheroplast into a rod, without previous division (this type of regeneration of spheroplasts has not been described so far); (b) after a single or double successive transverse division of the growing spheroplast (which corresponds to the finding of Nermut and Svoboda<sup>5</sup> on lysozyme spheroplasts); (c) after the fragmentation of a grown spheroplast.

We have not observed regeneration through growth and fragmentation of large long bodies, seen by Nermut<sup>6</sup> with penicillin spheroplasts.

After 7 h the regenerated rods covered more than half the preparation (Fig. 1).

In contrast, we have not observed any regeneration of spheroplasts in the *BI* strain of *E. coli*, in spite of the fact that even in this case about 30 per cent of spheroplasts grew and underwent many divisions in the preparations. It is obvious that the same factor in the same conditions can damage the cell wall to a varying degree in different strains.

In strain I7 glycine and penicillin spheroplasts presented a similar picture<sup>4</sup>. Both these types were on the whole constant, even in the broth without an osmotic stabilizer, and both rapidly regenerated into rods in a great majority of cases. In these qualities they differed from lysozyme spheroplasts.

Our observations accord with the view that glycine acts on the cell in a similar way as does penicillin, that is, it distorts the biosynthesis of its wall. The biochemical

nature of this inhibition in the two cases is, however, different.

### Production of a Soluble Substance by *Corynebacterium ovis*

*C. ovis* produces zones of haemolysis when grown on nutrient agar plates containing blood from various animal species, but no soluble haemolysin has been demonstrated and it would appear that the haemolytic effect is dependent on the presence of living bacteria in the haemolysate system<sup>1–3</sup>. The purpose of this communication is to note the production of a diffusible antigen by *C. ovis* which in certain circumstances is capable of causing haemolysis.

Three strains of *C. ovis* were inoculated into digest broth (modified medium of Carne<sup>4</sup>), incubated 7 days at 37° C and centrifuged until the supernatants were sterile. Two strains each of *C. equi* and *C. renale* were treated in similar manner. The sterile supernatants were pipetted into sealed wells, 6.0 mm in diameter, in 5 per cent blood agar plates which were incubated at 37° C.

After 24 h, a 3-mm wide zone of partial haemolysis appeared round the wells containing supernatants of *C. ovis* though not round those of *C. equi* and *C. renale*. The zone became more distinct on further incubation or the plate was refrigerated. The *C. ovis* preparations were active at 1/4 but not at higher dilutions.

In a second experiment, a *C. ovis* supernatant was mixed with an equal volume of a potent *C. ovis* antitoxin and shaken at 37° C for 30 min before testing by the method described here; haemolysis was completely inhibited. The antitoxin had no inhibitory effect on a sample of staphylococcal  $\beta$ -haemolysin, and normal rabbit serum without effect on either preparation when similarly treated (see Fig. 1). Filtration of 15 ml. of *C. ovis* supernatant through a Seitz EK pad removed its haemolytic power, did heating at 75° C for 15 min.

The three aforementioned properties possessed by this diffusible haemolytic agent were also found to be possessed by *C. ovis* toxin, and such similarity suggests that both the toxin and the haemolysin of *C. ovis* might well be the

## GENETICS

### Effect of Mitomycin C on Early Phenotypic Expression in the Transformation of *Diplococcus pneumoniae*

CONCERNING the transcription of genetic information by DNA, recent investigations, using systems of the transformation of *D. pneumoniae*<sup>1</sup> and infection with some bacteriophages<sup>2-4</sup>, have demonstrated that the DNA molecule consists of an informational and a non-informational strand. Guild and Robinson<sup>1</sup> succeeded in obtaining actions of denatured transforming DNA in CsCl density-gradient centrifugation which seemed to correspond to each polynucleotide chain, and they examined the time course of the appearance of cells possessing the new phenotype. It was observed that the expression of the new phenotype by one fraction was retarded for about one generation period compared with the other fraction. The messenger RNA synthesized after infection with bacteriophages<sup>2,3</sup>, or the RNA synthesized enzymatically in an *in vivo* system<sup>2,4</sup>, were examined for hybrid formation with polynucleotide chains separated in CsCl density-gradient centrifugation. The data suggested that the messenger RNA produced *in vivo* can form a ribonuclease-resistant hybrid with the unique polynucleotide chain of the primer DNA.

During the course of investigations on the transformation of *D. pneumoniae*, we have found evidence which supports this hypothesis. In the transformation of *D. pneumoniae* by DNA marked with streptomycin-

resistance, the new streptomycin-resistant cells appear about 10 min after DNA fixation, then they develop very rapidly and their number reaches the level of transformable cells after about 90 min<sup>5</sup>. The latter level remains almost constant up to this time. When mitomycin C in sub-lethal concentration (0.03  $\mu$ g/ml.) was added to a culture at the end of DNA fixation, the number of newly developed streptomycin-resistant cells was found not to reach the level of transformable cells even after prolonged incubation, for example, 3 h (Fig. 1). The time of appearance of these cells, and the rate of their development, did not vary significantly from the time and rate in the absence of mitomycin C. At the mitomycin level adopted in these investigations, there was no cellular multiplication or extensive death and there was also no significant increase in the amount of DNA when checked by the incorporation of <sup>3</sup>H-thymidine into the DNA fraction.

In order to confirm that the observed difference in the two levels is due to the presence of mitomycin C, an experiment was performed to follow the two levels after washing the drug during the course of transformation. A result is given in Fig. 2. It is evident that the level of streptomycin-resistant cells, which is lower than the level of transformable cells at 90 min, reaches that level in the period corresponding to one generation time of the cell. Repeated experiments showed that in the presence of mitomycin C, the ratio of the level of transformable cells to that of streptomycin-resistant cells was 1.5-2.0, indicating that approximately half of the population of transformable cells cannot express the new phenotype in the absence of DNA replication.

These results can be explained satisfactorily in the following way. Since in the absence of new DNA synthesis, half the population of transformable cells can express the new phenotype immediately and the other half cannot do so unless at least one round of DNA replication takes place, the former half would have fixed the informational strand and can synthesize new messenger RNA without DNA replication. The latter half, however, must have fixed the strand which is comple-

Fig. 1. Effect of mitomycin C on the development of streptomycin-resistant cells in the transformation of *D. pneumoniae*. DNA possessing streptomycin marker was added to a competent cell culture (0.5  $\mu$ g/ml.) and the latter was incubated for 7 min at 37° C. DNase (50  $\mu$ g/ml.) and mitomycin C (0.03  $\mu$ g/ml.) were added and the incubation was continued. At time intervals determinations were made in the usual way (ref. 7) with respect to the numbers of transformable cells (closed circles), streptomycin-resistant cells (open circles) and colony-forming cells (crosses). Selections were made at 100  $\mu$ g/ml. of streptomycin.

Fig. 2. Reversal of the effect of mitomycin C on the development of streptomycin-resistant cells in the transformation of *D. pneumoniae*. The experiments were performed in the same way as described in Fig. 1, except that the cell was washed after 90 min by centrifugation in the cold and reincubated in a fresh medium free from mitomycin C. In the figure the time of washing is indicated by an arrow. Symbols as in Fig. 1

mentary to the former half, and these cells come to be able to synthesize the messenger RNA after the informational strand is newly synthesized.

This view is based on two suppositions: (a) The recombination between the chromosomal DNA of recipient cells and the newly incorporated marker DNA must take place on a single-strand basis. This appears to be probable since Lacks<sup>6</sup> observed that a considerable part of the DNA comes to be single-stranded at the time of or immediately after incorporation into recipient cells of *D. pneumoniae*. (b) The genetic behaviour of both strands must be the same, so that both strands must be integrated with an equal probability.

## PSYCHOLOGY

### Taste Perception and the Menstrual Cycle

SENSITIVITY to the taste of quinine and 6-*n*-propylthiouracil (PROP) has been determined throughout one or more menstrual cycles in a group of nineteen subjects. Taste tests were carried out at the same time each day, 3 days per week, for periods ranging from 4 to 9 weeks. The subjects were apparently healthy and normal females and all but two were student nurses. Their ages ranged from 19 to 27 (average 20.7). Subjects were requested not to take drugs during the experiment. Four additional

subjects were excluded from the analysis because of illness or medication.

Taste thresholds (that is, the lowest concentrations the compounds which could be distinguished from water) were measured by the method of Harris and Kalmus<sup>6</sup> modified by Fischer *et al.*<sup>4</sup>. The method involved separation by taste of sets of eight cups, four of solution and four of distilled water, into two groups. The mouth was rinsed with water between tasting each cup. Dilute solutions were first tasted, followed by solutions of increasing concentration, until the subject could correctly sort the cups.

Test solutions were prepared so that each whole number solution was twice the concentration of the preceding one. In addition, solutions were prepared at the midpoint in the series between the whole numbers. Solution No. 14 of PROP was made by dissolving 1.0212 g of the compound in 1 l. of distilled water. Solution No. 13.5 was made by diluting 282.8 ml. solution No. 14 with 400 ml. water. Number 13 was one-half the concentration of No. 14 and 12.5 was one-half the concentration of 13. Solution No. 13 of quinine, an almost saturated solution, was prepared by dissolving 1.1744 g of 1-quinine sulphate (U.S.P.) in 1 l. of distilled water, and diluting as for PROP. The molar concentration of a solution of a given number was the same for either compound. Solution No. 14 had a concentration of  $6.0 \times 10^{-3}$  M; solution 13.5,  $4.24 \times 10^{-3}$  M; 13,  $3.0 \times 10^{-3}$  M; 12.5,  $2.12 \times 10^{-3}$  M; etc. The most dilute solution used had a concentration of  $1.62 \times 10^{-8}$  M.

The days in the menstrual cycle were numbered forward and backward from the first day of menstruation. In those instances in which two cycles were recorded, the days were counted from the first day of menstruation in the second cycle. In the present report, sensitivity within three phases of the cycle have been compared: the pre-menstrual (days -9 to -5), menstrual (day -1 to +4) and post-menstrual (days +6 to +10). The average scores of each subject during each of these phases are shown in Table 1. The scores of the initial two tests of each subject have been excluded from the analysis, as several showed an improvement with practice. The variances of the scores are also given in Table 1. When calculating these values the scores on days -3 to +5 were excluded, so that the variances refer to the intermenstrual phases.

Several subjects continued to improve after the first two tests and therefore the most conservative comparison was between the menstrual and post-menstrual phases of the cycle. The final column of Table 1 shows the differences in scores between these two phases. In the majority of individuals thresholds tended to be lower (that is, more sensitive) during the menstrual period. Analysis by the Wilcoxon matched-pairs signed ranks test shows that these differences are statistically significant. In the two-tailed test, for PROP  $P < 0.05$ , for quinine  $P = 0.05$ , and for both combined  $P = 0.003$ . The average increase in taste sensitivity during menstruation was 0.68 threshold for PROP and 0.45 for quinine. When the scores for PROP and quinine were considered together, 18 per cent showed a decreased sensitivity during the menstrual phase compared with the post-menstrual, 16 per cent showed no change and 66 per cent increased in sensitivity. An increase of 0.5 thresholds or more was shown by 47 per cent of the total sample, 18 per cent had an increase of 1 or more and 8 per cent increased by 2 thresholds or more.

The responses of the subjects were markedly heterogeneous. The most extreme change was shown by subject No. 13. Six days before the onset of menstruation her scores for both compounds changed markedly and reached maximum sensitivity on day -3. On this day she could distinguish from water the remarkably dilute concentration of  $3.24 \times 10^{-8}$  M PROP and  $1.62 \times 10^{-8}$  M quinine. Her scores had returned to their usual values by day +1.

Table 1. MEAN TASTE THRESHOLD SCORES FOR PROP (P) AND QUININE (Q) DURING THREE 5-DAY PHASES OF THE MENSTRUAL CYCLE

Days -3 to +5 in cycle were excluded from calculations of variance		Difference (post-menstrual minus menstrual)

Intermenstrual scores were equivalent to concentrations of  $3.31 \times 10^{-5}$  M PROP and  $5.86 \times 10^{-6}$  M quinine, representing a 1,024-fold change in PROP sensitivity and a 362-fold change in quinine. This subject was tested over two cycles and in both showed the same change immediately before the onset of menstruation. The change, if any, shown by other subjects was less dramatic and the majority reached maximum sensitivity after the onset of menstruation on days +1 to +5.

In large populations, taste thresholds for quinine follow a normal distribution, but the distribution for PROP is bimodal<sup>7</sup>. PROP and phenylthiourea (PTC) are related compounds and the taste responses to both are similar. Individuals can be classified as 'tasters' or 'non-tasters' of PROP according to whether their threshold lies below or above the antimode between thresholds 9 and 10 (ref. 3). Both tasters and non-tasters showed increased sensitivity at the time of menstruation. It is interesting that subject No. 2 was initially classified as a non-taster, but during menstruation she would clearly qualify as a taster. She changed from being unable to taste phenylthiourea paper (Carolina Biologicals, Inc.) to being able to taste it as bitter during menstruation. The degree of change associated with menstruation does not appear to be associated with the position of the individual's taste threshold on the population distribution curve.

Variations in numerous physiological and psychological characteristics have been correlated with the phases of the menstrual cycle, but reports on associated changes in sensitivity of the chemical senses are rare. Isolated instances of increased olfactory sensitivity during menstruation have been reported<sup>2,8</sup>, but no difference in taste threshold for PTC was observed in an investigation in which subjects were tested twice, once during the menstrual phase and again between periods<sup>4</sup>. Repeated testing under controlled conditions is a more sensitive method of examining constancy of the threshold. The wide variation in individual response shows that generalizations should be made with caution. Physiological and clinical changes associated with fluctuation in taste sensitivity in our sample are discussed elsewhere<sup>5</sup>.

## ANTHROPOLOGY

### Seriation of Quantitative Features in Late Pleistocene Stone Technology

THE possibility that some or all lithic assemblages are structured in such a way that those which are closely related can be arranged in chronological order, as suggested by Mellars<sup>1</sup>, is of great interest. If trends do exist in all the Mousterian assemblages of the two traditions considered by Mellars, it would be reasonable to expect that similar systematic trends would exist in other, and perhaps all, well-isolated assemblages of other periods and areas. The only prerequisite for examining this is a group of comparably analysed assemblages, close in space and time; these are notably present in the Aurignacian of the Vézère Valley (Table 1). The eight assemblages considered in Table 1 exhibited very convincing trends. In addition, a level of frequency of other traits (not attained in non-Aurignacian assemblages) was maintained. From this it can reasonably be concluded that some social continuity must exist between the makers of the assemblages.

Sites with several culture strata and assemblages of the same tradition can indicate seriation by themselves; for example, the 4 Solutrean assemblages from the Fourneau du Diable at Bourdeilles (Table 2). The stratigraphy shows the direction of the trends through time, in Tables 1 and 2. The upper Solutrean is further instructive; its characteristic development is distinctively different from two broadly contemporary layers of Pech de la Boissière, also upper Solutrean, 60 km to the south-east; and from the upper Solutrean of Jean-Blanc, 55 km to the south. This could be explained on the grounds that separate regional development was increasingly characteristic of the post-Mousterian stage. That this is the correct explanation is confirmed by comparing the Vézère Aurignacian seriation-line (Table 1), which covers only a 15-km stretch of country, with Table 3, a probably parallel development or seriation-subline for 4 assemblages from near Brive, only some 30 km to the east, and equally with the seriation line of 8 assemblages of the Bourdeilles-Charente region (found at three sites called Chevre, Vachons and Rois) not reproduced here.

A close examination of the series of traits, the frequency of which is shown in Table 1, reveals three main trends: Burins and Nosed/all Carinate scrapers which rise, and Grattoirs on Aurignac blades which fall. Two features—Buskoids (all carinates and buskate burins) which remain constant, and Aurignacian retouch which fall a little—are not found in other traditions (that is, seriation-lines) of the Vézère in comparable frequency. These traits may be termed 'line-fossils'.

In following the foregoing trends through 8 assemblages, stages of development (or seriation-zones) can be distinguished; 4 may be postulated for Table 1—A, B, C, D. Sub-zones may also be postulated, notably C1, 2 and 3,

Table 1. VEZERE AURIGNACIAN SERIATION-LINE

The figures are all recalculated from D. De Sonneville-Bordes' *Le Paléolithique Supérieur en Périgord*, 1960, and the numbers in the top columns refer to the designation of the tool types

Font Yves	1,237	1,077	18.8	14.8	16.1	14.8	19.2	7.7	9.2	13.3	9.9	0.7	1	C1-2

but these are less clearly identified than the full zones. For example, zone A has a markedly lower burin and higher type 6 frequency than B-D; C1 is different from C2, but not so certainly outside its range of variation. These zones may be used as chronological scales. Each zone tends to have a different characteristic trait or zone-fossil of its own, rising parabolically during the opening of the zone and falling at its end: zone A, Aurignac blades; zone B, strangulated blades; zone C, possibly Dufour bladelets; zone D, buskate burins.

Broadly speaking, well-excavated assemblages appear to seriate better than less competently gathered examples. Assemblages in Table 1 are not particularly well excavated. The thinner the culture stratum from which they come, the better. Metairie and Renne both contain material from two distinct layers—hence there are some obvious discrepancies. Assemblages with more than 500 tools seriate better than those with less, and no doubt most discrepancies would disappear if only assemblages in excess of 2,000 tools in the 1-72 group were used.

Difficulties rapidly arise in seriating assemblages of Perigordian I and later date, if material from an area larger than the Vézère Valley is used. The true reason for this is probably that only a continuity of assemblages of a particular ethnic group will seriate. The seriation-line or sub-line, though normally local, could continue in a second locality if the ethnic group were to move. The Aurignacian V of Laugerie Haute appears to follow from an Aurignacian sub-line in west-central France, the latest rather widely spaced elements of which are

Vachons 2, Fontenieux and Laugerie D. The localisation of seriation applicability seems much less in the Mousterian and much greater in the Solutrean and late

It might be expected that further discrepancies would arise from particular economic specializations, or seasonal variants being represented among the assemblage. Actually there is no indication of this, and Bouchud work on cervid teeth suggests that all-year-round occupation was the rule. The discrepancies which do remain are gratifyingly small in most cases. They may be due to certain limited but inevitable randomness in human behaviour. However, it is equally probable that they would become negligible if a larger number of better gathered assemblages and more sensitive analyses of the traits within them were used—with more than 2,000 characteristic tools for each, and no great time between them.

In the meantime the available evidence seems quite adequate to support a hypothesis that lithic assemblages studied by quantitative seriation, are suitable for tracing ethnic continuity, where they are present in sufficient concentration; and that they can be used as a method of relative dating, along with more classic physical and geological methods, when suitable circumstances are present.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, March 1

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY (in the Main Lecture Theatre, Department of Electrical Engineering, Exhibition Road, London, S.W.7), at 5.30 p.m.—Mr. L. Hix: "The Application of Automation to Railways".\*

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Control of Room Storage Heaters" opened by Mr. K. B. Rowson.

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. K. Stewartson: "The Boundary Layer".\*

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Professional Engineer and Man-Management" opened by Sir Wm. Carron.

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (joint meeting with the Microbiology Group, at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. A. K. Mills: "Research and Brewing" (Jubilee Memorial Lecture).

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Dr. Audrey Butt: "Peoples of the Forest and the Rivers".

## Tuesday, March 2

UNIVERSITY OF LONDON (at Wye College, near Ashford, Kent), at 4.45 p.m.—Dr. H. Kern (Zürich): "Plant Parasitic Fungi and Their Toxins".\*

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. D. A. Croney and Mr. J. A. Lee: "The Full-Scale Pavement Design Experiment on the A.1 at Alconbury Hill, Huntingdonshire".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. K. E. V. Willis: "Energy Storage".

FAUNA PRESERVATION SOCIETY (at the Zoological Society of London, Regent's Park, London, N.W.1), at 5.30 p.m.—Dr. David Snow: "Wildlife Conservation in the Galapagos".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. C. E. D. Taylor: "Diagnostic Applications of Immuno-Fluorescence". Fourteenth of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.\*

INSTITUTION OF MECHANICAL ENGINEERS, PROCESS ENGINEERING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Applications of Gas Turbines in the Process Engineering Industry".

## Wednesday, March 3

GEOLOGICAL SOCIETY OF LONDON (joint meeting with the Exploration and Production Group of the Institute of Petroleum, at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2 p.m.—Symposium on "The Geological Significance of Offshore Salt Basins Around Africa".

COLOUR GROUP (GREAT BRITAIN) (in the Large Theatre of the Physics Department, Imperial College, South Kensington, London, S.W.7), at 5.30 p.m.—Dr. W. A. H. Rushton, F.R.S.: "The Chemical Basis of Colour Vision and Colour Blindness" (Newton Lecture).

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, EDUCATION GROUP (at 9 Bedford Square, London, W.C.1), at 6 p.m.—Discussion on "Teaching of Control Engineering".

INSTITUTION OF MECHANICAL ENGINEERS, LUBRICANT AND WEAR GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Lubrication and Wear Design Memoranda—What is Wanted and How to Present It".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Sir Hugh Casson: "The Architecture of New Universities" (Alfred Borsom Lecture).

SOCIETY OF ENVIRONMENTAL ENGINEERS (at the Imperial College of Science and Technology, Exhibition Road, London, S.W.7), at 6 p.m.—Mr. E. Rivett: "Case Design for Service Equipment".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Northern Polytechnic Chemical Society, at the Northern Polytechnic, Falloway Road, London, N.7), at 7 p.m.—Prof. W. Klyne: "Optical Rotatory Dispersion".

ASSOCIATION OF THE WILLIAM PENGELLY CAVE RESEARCH CENTRE, in conjunction with IMPERIAL COLLEGE CAVING CLUB (in the Physics Department, Imperial College, London, S.W.7), at 8 p.m.—Mr. Colin Bristow: "The Resistivity Survey for Cavities in Devonian Limestone at Buckfastleigh, Devon".\*

## Wednesday, March 3—Thursday, March 4

ZOOLOGICAL SOCIETY OF LONDON (at Regent's Park, London, N.W.1), at 9.30 a.m. daily—Symposium on "The Cnidaria and Their Evolution".

## Thursday, March 4

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. L. S. Penrose, F.R.S.: "From Eugenics to Human Genetics".\*

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. J. Owen: "The Determination of Exchange Interactions by Magnetic Resonance Techniques" (Review Lecture).

UNIVERSITY OF LONDON (in the Wright-Fleming Institute Theatre, St. Mary's Hospital Medical School, Paddington, London, W.2), at 5 p.m.—Prof. M. Singer (Western Research University): "The Tropic Role of the Nervous System".\*

INSTITUTION OF CIVIL ENGINEERS, ENGINEERING MANAGEMENT GROUP (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Management Training from an Employee's Point of View", introduced by Mr. A. M. Sowden and Mr. G. H. Oversby-Powell.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. J. H. Westcott: "Research and Development in Control Engineering".

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Dr. C. R. Twidale (Adelaide): "Problems of South Australian Geomorphology".\*

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. R. Hobbs: "Disturbances of the Immunoglobulins". (Fifteenth of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 6 p.m.—Mr. I. Asboe Jorgensen: "Refrigeration in Modern Abattoirs with Special Emphasis on the Chilling of Pig and Beef Carcases".

INSTITUTION OF MECHANICAL ENGINEERS, RAILWAY ENGINEERING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Methods of Auxiliary Drive in Diesel Locomotives".

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 6 p.m.—M. Marcel Bruyere: "Modern Solutions of Coupling and Transmission Problems of Rotary Engines" (Eighteenth Louis Blériot Lecture).

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at West Ham College of Technology, Romford Road, London, E.15), at 7 p.m.—Prof. R. S. Nyholm, F.R.S.: "Metal to Metal Bonds in Complex Compounds".

## Friday, March 5

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 10 a.m.—Mr. J. Corcoran: "Current Views on Genito-Urinary Tuberculosis in Ireland".\*

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 11 a.m.—Symposium on "The Experimental Taxonomy of Flowering Plants".

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.45 p.m.—Annual General Meeting, followed by Dr. D. C. Garratt: "The Analyst in Pharmaceutical Industry".

INSTITUTION OF MECHANICAL ENGINEERS, THERMODYNAMICS AND FLUID MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Fluid Mechanics Films".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Stevenson Buchan: "The International Hydrological Decade".

## Saturday, March 6

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. J. D. Carthy: "Animal Communication".\*

## Monday, March 8

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 4.30 p.m.—Annual General Meeting. 5.30 p.m.—Dr. Mary Hesse: "The New Problem of Induction".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Prof. Peter Scott: "The Population Structure of Australian Cities".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. H. E. M. Barlow, F.R.S.: "Screened Surface Waves and Some Possible Applications".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. T. Barnard: "Micropaleontology: Past, Present, and Future".\*

SOCIETY OF CHEMICAL INDUSTRY (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. H. M. Stanley: "Some Achievements in Petroleum Chemicals" (7th Castner Memorial Lecture).

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN ASTRONOMY—The Registrar, The University, Manchester. 13, quoting Ref. 28/65 (March 3).

LECTURER or ASSISTANT LECTURER IN MATHEMATICAL LOGIC—The Secretary, The University, Aberdeen (March 5).

LECTURER or ASSISTANT LECTURER IN THE DEPARTMENT OF ZOOLOGY—The Registrar, The University, Liverpool, quoting Ref. CV/458 (March 5).

RANKINE CHAIR OF MECHANICAL ENGINEERING (Mechanics and Mechanism)—The Secretary of the University Court, The University, Glasgow (March 6).

ASSISTANT LECTURER IN THE DEPARTMENT OF GEOGRAPHY—The Secretary, University College, Gower Street, London, W.C.1 (March 8).

SENIOR LECTURER or LECTURER IN STATISTICS—The Secretary, The Queen's University, Belfast, Northern Ireland (March 9).

LECTURER, SENIOR LECTURER or READER IN ANIMAL HUSBANDRY at Makerere University College, University of East Africa, Uganda—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (March 10).

LECTURER (with interests in theoretical chemistry and/or spectroscopy) IN PHYSICAL CHEMISTRY—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (March 13).

ASSISTANT EXPERIMENTAL OFFICER/EXPERIMENTAL OFFICER (graduate in biochemistry, or chemistry and biology, and a general interest in the use of physico-chemical methods in biology) to assist in the Department of Cell Biology—The Secretary, John Innes Institute, Bayfordbury, Hertford, Herts (March 15).

POST-DOCTORAL RESEARCH FELLOW IN THE SCHOOL OF PHYSICAL SCIENCE to join a group working on the electron-microscopy of defects in solids, particularly at low temperatures—The Assistant Registrar (Establishment), University of Sussex, Stanmer House, Stanmer, Brighton, Sussex (March 15).

PRINCIPAL LECTURER IN SOCIOLOGY—The Principal, Lanchester College of Technology, Priory Street, Coventry (March 15).

SENIOR DEMONSTRATOR IN ZOOLOGY—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (March 15).

LECTURER IN APPLIED MATHEMATICS—The Secretary, The Queen's University, Belfast, Northern Ireland (March 16).

LECTURER IN CLINICAL PSYCHOLOGY IN THE DEPARTMENT OF PSYCHOLOGICAL MEDICINE—The Secretary, The University, Edinburgh (March 17).

SENIOR LECTURERS OR LECTURERS IN PURE MATHEMATICS, APPLIED MATHEMATICS AND STATISTICS at the University of Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (March 21).

CHAIR OF ZOOLOGY at Makerere University College, University of East Africa, Uganda—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (March 30).

SENIOR LECTURER OR LECTURER IN BOTANY; a SENIOR LECTURER and a LECTURER IN CHEMISTRY; a SENIOR LECTURER and a LECTURER IN MATHEMATICS; a SENIOR LECTURER OR LECTURER IN MICROBIOLOGY; a LECTURER IN PHYSICS; and a SENIOR LECTURER AND LECTURER IN ZOOLOGY at Njala University College, Njala, Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (March 30).

CHAIR OF BOTANY IN THE FACULTY OF SCIENCE of the University of Malaya, Kuala Lumpur—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London, March 31).

LECTURER/SENIOR LECTURER IN ANTHROPOLOGY at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, April 2).

LECTURER IN ORGANIC CHEMISTRY—Secretary of the University Court, The University, Glasgow (April 16).

LECTURERS (2) IN THE DEPARTMENT OF BIOCHEMISTRY—The Registrar, The University, Leicester (April 21).

AGRICULTURAL OFFICERS (nationals of the United Kingdom or the Republic of Ireland, with a degree in agriculture plus two years' postgraduate training or experience in tropical agriculture) in Malawi, to carry out the normal duties of an Agricultural Officer, which includes both European and African agriculture—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/134/02.

LECTURERS AND ASSISTANT LECTURERS IN CHEMISTRY—The Registrar, The University, Manchester, 13, quoting Ref. 29/65.

RESEARCH ASSISTANT (preferably with experience in animal behavioural techniques) IN PSYCHOPHARMACOLOGY—Prof. G. M. Carstairs, Department of Psychiatry, University of Edinburgh, 2 George Square, Edinburgh, 8.

RESEARCH ASSOCIATE (medical or non-medical graduate) IN THE DEPARTMENT OF MEDICINE, to join in a research project concerned with the metabolism of fat in arteries—The Secretary, Guy's Hospital Medical School, London Bridge, S.E.1.

SCIENTIFIC INFORMATION OFFICER (Abstractor) (with a degree in agricultural or natural sciences and ability to abstract from Russian)—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, near Maidenhead, Berks.

TECHNICAL ASSISTANT (preferably with experience in a physiological laboratory)—The Director, Medical Research Council's Department of Experimental Medicine, Tennis Court Road, Cambridge, marking envelope "Technical Assistant".

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

The University of Leeds. University Studies in Applied Science and Technology: an Introduction to the Degree Courses in the Faculty of Technology. Pp. 88. (Leeds: The University, 1964.) [1112]

The Study of Enzymes. By Prof. K. S. Dodgson. (An Inaugural Lecture delivered at University College, Cardiff, 28th April, 1964.) Pp. 17. (Cardiff: University of Wales Press, 1964.) 3s. 6d. [1112]

Ambassade de France, Service de Presse et d'Information. Statement made by the Minister of Foreign Affairs in the National Assembly, 3rd November, 1964. Pp. 16. The French Press. Pp. 15. (London: Ambassade de France, Service de Presse et d'Information, 1964.) [1112]

The Electrical Research Association. Report No. 5026: Dielectric Effects of Flaws in Hydrogen Bonding III. By Dr. Vera Daniel. Pp. 13+9 figures. (Leatherhead: Electrical Research Association, 1963.) 12s. 6d. [1112]

Ministry of Housing and Local Government. Welland and Nene Rivers: Hydrological Survey (Hydrometric Areas 31 and 32). Pp. v+80. (London: H.M. Stationery Office, 1964.) 17s. 6d. net. [1112]

Discovery Reports. Antarctic and Subantarctic Mollusca: Amphineura, Scaphopoda and Bivalvia. By R. K. Dell. Pp. 93-250+plates 2-7. 100s. net. Larves de Ceriantales. By E. Leloup. Pp. 251-307+plates 8-21. 75s. net. (London and New York: Cambridge University Press, 1964.) [1112]

Thorium Limited: Fifty Years of Progress. Pp. 16. (London: Thorium Limited, 1964.) [1112]

Office of Health Economics. The Pharmacist in Society. Pp. 32. (London: Office of Health Economics, 1964.) 2s. [1112]

### Other Countries

United States Department of the Interior: Geological Survey. Water-Supply Paper 1669-CC: Natural Sources of Salinity in the Brazos River, Texas, with particular reference to the Croton and Salt Croton Creek Basins. By R. C. Baker, L. S. Hughes and I. D. Yost. Pp. vi+81+plates 1-4. Water-Supply Paper 1671: Magnitude and Frequency of Floods in the United States. Part 1-A: North Atlantic Slope Basins, Maine to Connecticut. By A. Rice Green. Pp. x+260+plate 1. Water-Supply Paper 1779-B: Ground-Water Conditions in the Proposed Waterfowl Refuge Area near Chapman, Nebraska. By C. F. Keech. With a section on Chemical Quality of the Water by P. G. Rosene. Pp. v+55+plates 1-6. Water-Supply Paper 1779-X: Quality of Delaware River Water at Trenton, New Jersey. By Leo T. McCarthy, Jr. and Walter B. Keighton. Pp. iv+51+plate 1. Water-Supply Paper 1785: An Appraisal of the Possibilities of Artificial Recharge to Ground-water Supplies in Part of the Roswell Basin, New Mexico. By Ward S. Motts and R. L. Cushman. Pp. v+85+plates 1-7. (Washington, D.C.: Government Printing Office, 1964.) [1612]

India: Council of Scientific and Industrial Research. Central Building Research Institute Annual Report, 1963-1964. Pp. ix+62+15 photographs. (Roorkee: Central Building Research Institute, 1964.) [1612]

Annals of the New York Academy of Sciences. Vol. 116, Article 3: The Acute Inflammatory Response. By W. G. Spector, Albert S. Gordon and 39 other authors. Pp. 747-1084. 6 dollars. Vol. 119, Article 2: Problems of Cooley's Anemia. By Harold Fink and 76 other authors. Pp. 369-860. 8 dollars. (New York: New York Academy of Sciences, 1964.) [1612]

Union Radio Scientifique Internationale. XIV<sup>e</sup> Assemblée Générale, Tokyo, Sept. 9-20, 1963. Vol. XIII-4: Commission IV—Magnetosphere. Pp. 147. Vol. XIII-5: Commission V—Radioastronomie. Pp. 200. Vol. XIII-7: Commission VII—Radioélectronique. Pp. 169. (Bruxelles: Union Radio Scientifique Internationale, 1964.) [1612]

Japan. Meteorological Research Institute: Oceanographical Laboratory. Collected Reprints, Vol. 8. Reprints Nos. 132-153. (Mabashi, Suginami, Tokyo: Meteorological Research Institute, Oceanographical Laboratory, 1964.) [1612]

List of Papers published by the Members of the Research Institute for Iron, Steel and other Metals, Tohoku University, 1963. Pp. 25. (Sendai: The Research Institute for Iron, Steel and other Metals, Tohoku University, 1964.) [1612]

Australia: Commonwealth Scientific and Industrial Research Organization. Annual Report of the Irrigation Research Laboratory, 1963-64. Pp. iv+31. (Griffith, N.S.W.: Commonwealth Scientific and Industrial Research Organization, 1964.) [1612]

India: Council of Scientific and Industrial Research. Directory of Indian Scientific Periodicals, 1964. Pp. ix+133. (Delhi: Indian National Scientific Documentation Centre, 1964.) [1612]

Commonwealth of Australia: Bureau of Mineral Resources. The Australian Mineral Industry, Vol. 17, No. 1. Part 1: Quarterly Review. Part 2: Quarterly Statistics. Pp. iv+31. (Canberra City, A.C.T.: Bureau of Mineral Resources, 1964.) 6s. [1612]

Australia: Commonwealth Scientific and Industrial Research Organization. Annual Report of the Division of Physics, 1963-64. Pp. iv+29. (Sydney: Commonwealth Scientific and Industrial Research Organization, 1964.) [1612]

Australia: Department of National Development. Bureau of Mineral Resources, Geology and Geophysics. Report No. 75: The Geology of the Bowutu Mountains, New Guinea. By D. B. Dow and H. L. Davies. Pp. iv+31+2 plates. (Canberra City, A.C.T.: Bureau of Mineral Resources, Geology and Geophysics, 1964.) [1612]

New Zealand: Department of Civil Aviation. New Zealand Meteorological Service. The Climate and Weather of Northland, New Zealand. By J. F. de Lisle and I. S. Kerr. (Reprinted from *National Resources Surveys*, Part 3—Northland.) Pp. 14. (Wellington: Government Printing Office, 1964.) [1612]

Australia. Twelfth Annual Report of the Australian Atomic Energy Commission for the year ended 30th June, 1964. Pp. 80. (Coogee, N.S.W.: Australian Atomic Energy Commission, 1964.) [1612]

Australia: Commonwealth Scientific and Industrial Research Organization. CSIRO and Engineering in Industry. Pp. 48. (Melbourne: Commonwealth Scientific and Industrial Research Organization, 1964.) [1612]

Annual Report of the Geological Survey, Borneo Region, Malaysia, 1963. By R. A. M. Wilson. Pp. vii+230+47 plates. (Kuching, Sarawak: Geological Survey Department, 1964.) 3 Malayan dollars; 7s. [1612]

United Nations. Report of the United Nations Scientific Committee on the Effects of Atomic Radiation. (General Assembly. Official Records: Nineteenth Session, Supplement No. 14, A/5814.) Pp. iv+120. (New York: United Nations, 1964.) 1.50 dollars. [1612]

United States Department of the Interior: Geological Survey. Professional Paper 501-C: Geological Survey Research 1964, Chapter C. Pp. vi+197. (Washington, D.C.: Government Printing Office, 1964.) [1612]

Publications of the National Research Council of Canada, Supplement, 1958-1963. Compiled by the Staff of the National Science Library. Pp. v+433. (Ottawa: National Research Council of Canada, 1964.) [1612]

INFLUENCE OF PARTICLE SIZE ON DECOMPOSITION OF RED ALDER AND DOUGLAS FIR SAWDUST IN SOIL. By J. L. Neal, jun., Prof. W. B. Bollen and Dr. K. C. Lu . . . . .	991

(Continued overleaf)

**UNICAM****SP.800**

spectrophotometer  
for routine U.V. analysis  
with automation accessories

***Save operator time, increase speed and efficiency with Unicam automation for:***

**ENZYME REACTION RATES**

**LIQUID COLUMN CHROMATOGRAPHY**

**ALL ROUTINE ULTRAVIOLET AND  
VISIBLE SPECTROSCOPY**

*Please send for descriptive brochure*

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as *the* outstanding U.V. spectrophotometer. Additionally Unicam now offers automation equipment which provides:

**AUTOMATIC** interchange of up to 4 sample and 4 reference cells

**AUTOMATIC** re-cycling over any preselected wavelength range

**AUTOMATIC** recordings at predetermined time intervals

# LETTERS TO THE EDITOR

Page

## ASTRONOMY

- Disappearance of the Polar Cap on Mars in 1956 after a Solar Flare with Ejection of Particles.—Dr. L. Křivský, Dr. J. Čech and Dr. J. Sadil . . . 994

## PHYSICS

- Domain Structures in Liquid Crystals, induced by Electric Fields.—G. Elliott and J. G. Gibson . . . 995  
Electrification of Porous Alumina on Desorption of Gases.—Alberto C. Montefinale, Dr. Gianna L. Petriconi and Dr. Henry M. Papée . . . 996  
Single Bi-particle Elastic Collisions of Fast Protons with Metals.—Prof. Rafi Mohammed Chaudhri, Mustafa Yar Khan and M. Munawar Chaudhri . . . 997

## GEOPHYSICS

- Role of Plasma Instabilities in Auroral Phenomena.—Bruno Coppi . . . 998

## GEOCHEMISTRY

- Formation of Cobalt (III) in the Amorphous FeOOH.  $n\text{H}_2\text{O}$  Phase of Manganese Nodules.—Roger G. Burns . . . 999

## METALLURGY

- Grain Size of Ausformed Steel.—Dr. K. F. Hale and Dr. D. McLean . . . 1000

## MINERALOGY

- Mass Spectrometric Analysis of the Gas evolved from Some Heated Natural Minerals.—C. G. Barker . . . 1001

## CHEMISTRY

- Measurement of Adsorption Isotherms by a Gas Chromatographic Technique.—P. J. Kipping and D. G. Winter . . . 1002  
'Stereo-chromatography': a New Method for Chemical Identification and Preparative Isolation.—Carl J. Pfeiffer and Joseph R. Debro . . . 1003  
An Oil-Wax-Surfactant System for retarding the Evaporation of Water.—Dr. R. C. Fox . . . 1004  
Solubility of Polyethylene Terephthalate.—L. Cottam and Dr. R. P. Sheldon . . . 1005  
Temperature Dependence of Contact Angles.—M. C. Phillips and Dr. A. C. Riddiford . . . 1005

## BIOCHEMISTRY

- Biological Activity of Retinoic Acid Ester in the Domestic Fowl: Production of Vitamin A Deficiency in the Early Chick Embryo.—Dr. J. N. Thompson, Dr. J. McC. Howell, Dr. G. A. J. Pitt and Catherine I. Houghton . . . 1006  
Decomposition of Structural Polysaccharides of Bacteria by Marine Micro-organisms.—Dr. R. Mitchell and Z. Nevo . . . 1007  
Free Radicals derived from Amines and Amino-acids in some Reactions of Ninhydrin.—Dr. J. C. Orr . . . 1008  
Tumours in the Rat after Injection of Preneoplastic and Neoplastic Nucleic Acids.—Prof. A. Cantarow, Dr. T. L. Williams and Dr. J. W. Goddard . . . 1010  
Denaturation of Rennin; Effect on Activity and Molecular Configuration.—Dr. G. C. Cheeseman . . . 1011

## PHYSIOLOGY

- Comparison of Multiple-unit and Electroencephalogram Activity recorded from the same Brain Sites during Behavioural Conditioning.—Dr. Jennifer S. Buchwald, Prof. E. S. Halas and Sharon Schramm . . . 1012  
Salivary Secretion of Caesium-131.—Prof. Franz K. Bauer, Nancy Telfer and Brita Hetter . . . 1014  
Distribution of Dendrites in Retinal Ganglion and Cortical Stellate Cells.—R. F. Fisher . . . 1015  
Delayed Onset of Proteinuria in Ageing Hypophysectomized Rats.—Dr. A. V. Everitt and Leanna K. Duvall . . . 1016  
Small  $p\text{CO}_2$  Change and Neuronal Synaptic Activation.—Dr. N. Chalazonitis and Prof. G. G. Nahas . . . 1016

## PHARMACOLOGY

- A Sensitive Assay for Inhibitory Agents of Pleuropneumonia-like Organisms.—Dr. C. W. Godzeski and D. E. Pavey . . . 1017  
Propoxate (R7464): a New Potent Anaesthetic Agent in Cold-blooded Vertebrates.—D. Thienpont and C. J. E. Niemegeers . . . 1018  
Effect of Reserpine on Atrial and Ventricular Rates in Atrial Fibrillation in Man.—Prof. Walter Modell and Allen E. Hussar . . . 1019

## HAEMATOLOGY

- Polypeptide Chains of Buffalo Haemoglobins.—A. S. Balani and J. Barnabas . . . 1019  
 $^{32}\text{P}$ -labelling of Nucleotides from a Soluble Erythrocyte-membrane Fraction devoid of Haemoglobin.—Gunnar Ronquist and Prof. Gunnar Ågren . . . 1021

## IMMUNOLOGY

- Vitamin A-induced Rejection of Autografts and Homografts.—Dr. D. Nelken, E. Pick, M. Gabriel, W. Bitterman and J. H. Boss . . . 1022

## PATHOLOGY

- Staphylococcal Interference in Infections in Embryonated Eggs.—Dr. William R. McCabe . . . 1023  
Non-specificity of Thioflavine-T as an Amyloid Stain.—Brian McKinney and Chandra Grubb . . . 1023  
Phenylalanine Tolerance Test for Heterozygous Carriers of Phenylketonuria.—Prof. Eino Nelson . . . 1024

## BIOLOGY

- Nutrient Content of Rainwater in the Gambia.—I. Thornton . . . 1025  
High Photosynthetic Efficiency in a Low-latitude Environment.—Dr. J. E. Begg . . . 1025  
Auxin-induced Reversal of Geotropic Response in Onion Seedlings.—Prof. B. M. Johri, Sipra Guha and Dr. S. C. Maheshwari . . . 1026  
Xylem Sap Composition in Woody Plants.—Dr. T. M. Morrison . . . 1027  
Spider Genus *Dysdera* (Araneae, Dysderidae).—J. A. L. Cooke . . . 1027  
Tantalum and Niobium in Ascidians.—Prof. N. Kokubu and Dr. T. Hidaka . . . 1028  
Toxicity of Rubber Stoppers to *Daphnia magna* Straus.—Dr. J. H. Hubschman and R. A. Engel . . . 1029

## FORESTRY

- Heterophyllous Shoots in *Betula papyrifera*.—Dr. J. Johanna Clausen and Prof. Theodore T. Kozlowski . . . 1030

## ENTOMOLOGY

- Structure-activity Relationships among Insecticidal Compounds derived from Chlordane.—Dr. G. T. Brooks and A. Harrison . . . 1031

## MICROBIOLOGY

- Nomenclature of Living Parasite Material.—W. H. R. Lumsden and Gillian J. C. Hardy . . . 1032  
Distribution of Respiratory Quinones in 2,5-di-tert-amyl-p-benzoquinone-sensitive and -resistant Bacteria.—J. W. May and R. H. Houghton . . . 1032

## VIROLOGY

- Activity of 6-Aminonicotinamide against Vaccinia Virus *in vitro*.—F. J. Stanfield and J. D. McColl . . . 1033  
Haematological Changes in Viral (MHV-3) Murine Hepatitis.—Prof. M. Piazza, F. Piccinino and F. Matano . . . 1034

## GENETICS

- Inheritance of Self-incompatibility and Brown Keel Tip in *Lotus corniculatus* L.—Prof. J. S. Bubar and R. K. Miri . . . 1035  
Taste Sensitivity to Phenyl-thio-carbamide and Endemic Goitre among Pewenche Indians.—Prof. Edmundo Covarrubias, Dr. José Barzelatto, Dr. Carlos Stevenson, Dr. Eduardo Bobadilla, Dr. Antonio Pardo and Dr. Christian Beckers . . . 1036

# No other stereoscopic microscope incorporates so much for so little

The Varimax MST 130

**Compare these features:** For only £167.10.0 you can purchase a precision-made stereoscopic instrument with a magnification range from **4x to 100x** and a free working distance up to **100 mm**. In addition, standard specification includes incident and transmitted illumination • A fully comprehensive range of accessories includes: Mechanical and shifting stages • Insect holders • Vertical illumination prisms

*Table of magnification, field of view and working distance*

eyepiece 0.63	1.0	1.6	2.5	4.0	work. dist.
6.3x 44mm	6.3x 28mm	10x 17.5mm	16x 11mm	25x 7mm	100mm

## Gas Chromatograph Test Set & Reference Signal Source

enables the Chemist or Instrument Engineer to check quickly the operation and performance of his complete Gas Chromatograph equipment. If the equipment is not operating correctly, it will quickly localise the faulty section. No electrical knowledge is necessary to use this Test Set, which is suitable for Flame Ionisation, Thermistor type and Katharometer Gas Chromatographs.

Please write for details now:-

## EDUCATING THE WHOLE SCIENTIST

THE autumn 1964 issue of *Daedalus* is devoted to the topic "The Contemporary University: U.S.A.". Some of the essays, such as Prof. W. C. Devane's "The College of Liberal Arts" and Prof. F. Heimberger's "The State Universities", are concerned specifically with conditions in the United States. Dr. Clark Kerr's "The Frantic Race to Remain Contemporary" is essentially an exposition of the argument for the multi-versity presented in his Godkin Lectures in 1963 and published under the title "The Uses of the University". Peter H. Rossi's essay, "Researchers, Scholars and Policy Makers: the Politics of Large-scale Research", is likewise concerned with the American scene, and almost exclusively with the effect of the development of research centres for social science within the university environment on the organization of a university, but in Dr. R. S. Morison's "Foundations and Universities" the wider implications are much more apparent.

Other essays have a bearing and interest that obviously extend far outside the United States. Dr. J. M. Ziegler's discussion of continuing education in the university is perceptive and highly pertinent to discussions on adult education which are current in Britain, and Dr. P. Weiss's essay on science in the university is of outstanding interest to the scientist, as well as to the university administrator and others. This issue also includes Dr. J. A. Stratton's commencement address to the Massachusetts Institute of Technology last June, which touches on the same broad theme of the purpose and function of the university in modern society.

For all his faith in and dedication to the work and methods of science, Dr. Stratton does not believe that we can any longer take for granted the thesis that technology is the driving force of progress. A blind confidence in the inevitable good of material progress can lead only to disillusionment. Technical advances have now such complex and indirect effects that it is only by an examination of their impact on society as a whole that we can judge the degree of progress from a particular innovation. Arguing in lines made familiar through the Buchanan Report, for example, Dr. Stratton urges that many of the problems of society to-day will yield only to planned collaborative attacks focused on clear objectives and based on concerted action.

It is from this point of view of the dependence of success on the joint contributions of physical and biological scientists, of economists and political scientists, engineers and architects, historians and philosophers, that Dr. Stratton turns to the university as the one institution capable of meeting this highest intellectual challenge of our time—that of stimulating or welding these components of learning into systems of understanding. Only within the framework of the university do we find the wide range of interests, a common ground for the exchange of ideas, a forum of discussion for scholars who draw on the arts and humanities as well as on science and technology. This is particularly true of institutions like the Massachusetts Institute of Technology, and Dr. Stratton believes that they cannot escape the responsibility of participating in the solution of problems touching deeply the total welfare of society.

This is manifestly recognized, for example, by the Imperial College of Science and Technology, but Dr.

Stratton goes on to urge that the changing role of science and technology, arising out of their penetration into every domain of human affairs, carries, in a free society, personal and individual responsibility, as well as that which properly falls on the institutions of society—on Government, industry and university. Dr. Stratton here addressed himself specifically to his own students, but his emphasis on personal and professional responsibility, like that on the responsibility of the university itself, is in harmony with Dr. Weiss's view of the place of science in the university. Dr. Weiss recognizes that examination of the growing impact of science on the universities is a continuous process, which involves finding ways for the university to accommodate the legitimate claims of science, and at the same time protecting the university against expansion of the scientific sectors beyond a stress limit at which the ideal of a university as a cohesive body would collapse. He deplores the antagonism inherent in the idea of 'two cultures' and seeks to eliminate such discords and contentions, while admitting the lack of symmetry in mutual relations between scientists and non-scientists which is the core of Lord Snow's argument.

Pointing out that no one scientist can any longer claim the authority to act as spokesman for the whole of science, Dr. Weiss nevertheless regards this staggering internal diversity of science as an asset, as an essential factor in the role of science in education. There the significant feature of science lies in the spiritual or cultural values it imparts. The scientific method teaches man to discipline his thinking and his actions based on thought. Broadly applied, it can clear away the underbrush of superstition and prejudice, correct or eliminate complacency and cocksureness, inspiring fresh resolves to search and strive rather than to conform, checking the deadening effect of mechanization.

Science, in Dr. Weiss's view, is thus a major integral factor of our culture, not just a service function; its spirit is of as much concern to man as its products. Science and the humanities are seen not as opponents but as partners in a common enterprise, and it is wrong to single out the scientist as specially benefiting from a broad liberal education, which aims chiefly to provide educated, responsible and judicious citizens in general. Nevertheless, this does not necessarily mean that the basis of general education should be the same for all, even for all who contemplate a career in science.

That point assuredly requires to be considered more carefully in the expansion of higher education in Britain, for it bears on the nature of institutions as well as the content of courses. Dr. Weiss believes that the conflict between the demand for early technical specialization and the demand for a broad general education to safeguard the creative scientist (as well as in the interest of adaptability) can be resolved if sufficient forethought is given to the specific needs of both streams for a broad general basis. Surrender to the growing demands for professional or vocational training at the expense of breadth and flexibility, however, would be fatal, above all to the maintenance of a supply of men of science of independence and integrity, vision and courage.

It is in this belief that Dr. Weiss proceeds to discuss the question not what is a university but who is 'the university', and urging the necessity for the university-

and the scientific establishment to accept the great variety of form which characterizes them both and to seek to effect the most congruous match between these respective patterns. He considers that only a collective integrated system of plural universities with diverse functions can fulfil the ideal overall function of 'the university'. He visualizes the university of the future as being a community of scholarly institutions instead of a community of scholars.

This idea is implicit in certain trends in Britain, for example in the way in which groups of universities are sharing particularly costly equipment, and in comments such as are to be found in the report on the organization and management of research regarding the location of research associations and research institutes or stations. It has clearly been taken into account in planning the specific activities of new universities, at least to the extent of recognizing that it is wiser for a new university to be selective in the fields of study it offers and not attempt to cover the whole field of knowledge. Dr. Weiss observes that every institution has certain areas of strength which it tends to cultivate more than others. The significant difference between this outcome of accident and necessity, which marks the present situation both in the United States and in Britain, and the orderly scheme he envisages for the future, is that in the past differentiation between the universities has been piecemeal and incoherent so that the various pieces do not fit together to form the harmonious whole which he advocates.

That ideal system cannot be achieved unless a certain number of universities come together to review their respective functions and capabilities and, with the minimum infringement of independence or autonomy, work out a collective plan so that collectively they supplement each other over the whole field of knowledge. Such efforts at integration would be guided by three main considerations: the filling of significant gaps; the correction of serious disproportions; and the lessening of redundancy, particularly where merging isolated units would lead to increased strength. Such measures would, he holds, restore the very principle of continuity, unity and universality of knowledge implicit in the idea of a university, and could also contribute to maintaining the highest possible standards of education for responsible leadership which remains a prime obligation of the universities.

Looking next at the functions of a university in this context before he discusses the place of science, Dr. Weiss distinguishes four essential major functions: the preservation, critical interpretation and synthesis of existing knowledge; furthering the acquisition of new knowledge and developing the necessary intellectual and technical tools; training in the application of existing knowledge to the practical needs of man; and transmitting and disseminating knowledge and its implications and applications. He believes that a community of institutions such as he advocates would be in a uniquely favourable position to give balanced attention to all these functions. In regard to the first, for example, greater concern with the history, structure and cultural values of science has created not only an opportunity but also a genuine demand for a far more active interplay between the sciences and the humanities in education, with benefit to the humanist as well as to the scientist.

The second function involves more difficult issues through the risk of disproportionate expansion of scientific research. Here Dr. Weiss emphasizes the risks of excessive concern with publication and of inflating the numbers of

research workers with those possessing little aptitude for or interest in, scientific research. He also stresses the need for the universities to resist pressure to undertake more sharply-delineated 'project' or 'contract' research than or may be useful for training purposes. He sees the main safeguard against the latter in the participation of experienced scientists in the formation of policy and evaluation of programmes, and stresses the importance of scientist accepting such administrative responsibilities for maintaining standards and efficiency. The main motive for scientific research in the university, Dr. Weiss maintains should be to turn out scientific personnel, not scientific products.

It is this, of course, that really links research with teaching, and Dr. Weiss, in a passage reminiscent of an early report from the University Grants Committee urges that every kind of institution of higher education including teacher training colleges, would gain from having some degree of scientific research conducted on its campus, motivated not chiefly by the need to train specialists but by the disciplinary value of research in developing critical thinking. That is a point of view to be given more weight than it appears at present to be receiving. In discussing the question of how research might figure more prominently in teaching and training those who are not destined for a career in research, Dr. Weiss commends the encouragement of elementary research in the schools and a critical revision, if not reduction, of the content of curricula. He does not suggest that there is any specific ratio or formula for the proportion of research to teaching, but reminds us that this depends alike on the stage reached by the student as well as on the aptitude of the teacher, and once again he joins issue with the tendency to relate academic status to the range or quantity of published papers, to the neglect of the quality of teaching.

Finally, Dr. Weiss emphasizes the vital importance of adult education both for the universities and the advancement of science, and the necessity for the universities to participate with real imagination and determination in extramural work to that end. He offers no specific recommendations in this field, and it is indeed the general character of his observations that makes them so pertinent for the discussions now proceeding on the expansion of higher education in Britain and the re-shaping of the relations between science and society as well as its organization within the civil administration. The main issues are clearly discerned, but the details and the particular measures to be concerted to resolve the problems depend on the special conditions of the country or society they are intended to serve. Both Dr. Stratton and Dr. Weiss give warnings and counsel that we in Britain would be wise to heed.

## THE WIND THAT SHAKES THE BARLEY

### Barley Genetics I

(Proceedings of the First International Barley Genetics Symposium, Wageningen, 26-31 August, 1963.) Pp. xxii + 387. (Wageningen: Centre for Agricultural Publications and Documentation, 1964.) n.p.

*BARLEY Genetics I*, the record of the first international symposium on barley genetics, contains 35 papers all in English, presented under eight main headings.

The origin and phylogeny of barley are dealt with in three papers. F. Kh. Bakhteyev (U.S.S.R.) reviews the

various hypotheses which have been put forward and suggests that an experimental test of existing as well as of new hypotheses is needed. R. Takahashi (Japan) presents the results of his survey of the geographical distribution of the genes for brittle ear, resistance to powdery mildew and spring habit and agrees with Bakhteyev on the monophyletic origin of barley. D. Zohary (Israel), after suggesting that both *Hordeum agriocrithon* and *H. lagunculiforme* are of hybrid origin, agrees that *H. spontaneum* may be the sole progenitor of cultivated barleys. The organization of international expeditions as suggested by Bakhteyev is under consideration and it is likely that material collected will be available to all countries.

Five papers are devoted to mutation. R. A. Nilan, C. F. Konzak, R. E. Heiner, and E. E. Froese-Gertzen (United States), in a paper on chemical mutagenesis in barley, discuss the problems of technique and interpretation in measuring the effects of mutagen treatment and review recent work with alkylating agents. Special attention is directed towards factors affecting mutagenic action of various chemical agents. A. Hagberg and G. Persson (Sweden) survey the application of induced mutations to barley genetics, taxonomy and plant breeding, with special reference to the results of Swedish mutation research. E. A. Favret (Argentina) compares the mutagenic efficiency of ethyl methane sulphonate (EMS) with that of ionizing radiations, and describes their interaction in combined treatments. A. Moës (Belgium) states that EMS before reaching lethality induces in the  $X_1$  leeper physiological damage than X-rays and induces a higher degree of sterility. U. Lundqvist (Sweden) describes the induction of mutations in barley pollen by means of ultra-violet and X-rays.

The section on chromosome aberrations deals with macromutations, aneuploidy and polyploidy. R. T. Lamage (United States) discusses the uses of translocations in genetic research and their application in the reduction of trisomies. T. Tsuchiya (Japan) describes his work on the production of trisomies from triploids and translocations in diploids. E. Reinbergs (Canada), in a paper on autotetraploids, emphasizes the high degree of fertility found and the few positive results obtained in attempts to reduce this by the introduction of structural rearrangements in the chromosomes.

During the symposium, a group of workers interested in linkage investigations attempted to produce a map of the chromosomes of barley. It is obviously incomplete and probably inaccurate, but useful. In this connexion, D. W. Robertson (United States) presents linkage data for many new genes together with their proposed positions on the chromosomes. Detailed linkage investigations are also given by S. B. Helgason (Canada) and G. Holm (Sweden). In order to provide international co-ordination of genetic investigations in barley, procedures for the nomenclature and handling of genetic stocks are proposed and the names and addresses of the proposed co-ordinators are given.

A single paper on "Interspecific and Intergeneric hybrids in *Hordeum*", by T. Rajhathy, J. W. Morrison and S. Symko (Canada), deals primarily with species relationships based on evidence obtained during the past ten years in Ottawa and includes a review of most of the published work on this subject.

One of the largest sections is that on disease resistance. Here eight papers are presented. J. G. Moseman (United States) deals with the complementary reaction between host conditioning and those governing the pathogenicity of the powdery mildew fungus. In two further papers on powdery mildew, Y. Koltin, R. Kenneth and I. Wahl (Israel) describe physiological specialization of the pathogen in Israel and E. P. Baker (Australia) presents further evidence for an allelic series conditioning resistance to mildew at the Algerian locus. C. W. Schaller (United States) discusses barley yellow dwarf virus and barley stripe mosaic virus and their relationship to other

hosts such as oats and grasses. J. W. Gibler and Ch. F. Krull (United States) present a short note on the inheritance of resistance to "enanismo", a virus or virus-like dwarfing disease causing serious losses in susceptible varieties of barley, wheat and oats. J. M. Poehlman (United States) gives a brief description of breeding for resistance to loose smut, and J. C. Zadoks (Holland) deals with the use of race nurseries in cereal resistance breeding. The section is completed by a second contribution from J. G. Moseman on the present status of plant pathological research in his country.

There are three papers on physiological and quantitative genetics. Ch. R. Olien (United States) discusses the problems associated with winter hardiness in barley and describes a new method of evaluating stresses. J. E. Grafius (United States) presents a geometric scheme for the construction of populations which may provide the maximum chance of success in an acceptable phenotype in breeding for yield when only a limited number of plants is selected on the basis of more readily observable traits. G. A. Weibe (United States) surveys the contributions of DDT and its analogues to the genetics and breeding of barley.

The final section of this symposium, on breeding techniques and malting quality, is the largest and contains nine papers. G. D. H. Bell (Britain) gives a comprehensive review of general breeding techniques. C. A. Suneson (United States) discusses the use of populations in breeding and possible economic uses of heterosis. Five papers are devoted to malting quality and cover the methods and achievements of breeders in Western Europe (A. Lein, Germany); methods of testing for malting quality and investigations into its inheritance (R. N. H. Whitehouse and E. T. Whitmore, Britain); the development of a system for evaluating malting quality of new strains, and methods of selection for malting quality (D. Glas, W. Wilten and M. L. Wijvekate, Holland); breeding for malting quality (A. R. Raw, Australia) and the production of improved malting varieties with increased resistance to lodging and mildew (J. Lekeš, Czechoslovakia). The phenotypic expressivity of genotypes in different environments is discussed by K. Gotoh (Japan), and K. W. Finlay (Australia) presents an investigation on the measurement and significance of adaptation in barley breeding.

The book is a valuable collection of papers with, in most cases, copious references. The discussion following each section is reasonably well reported.

E. V. B. WILSON

## ENVIRONMENTAL STUDY

### The Biology of the Living Landscape

An Introduction to Ecology. By Prof. Paul B. Sears. Pp. 176. (London: George Allen and Unwin, Ltd., 1964.) 21s. net.

FROM its title one might imagine this to be a book concerned specifically with the landscape of the author's native America—a biologist's book, having perhaps only a limited application to the landscape of Britain. But this is far from being the case. Prof. Sears has far wider aims: he sets out to trace the emergence of ecology as a science, and to bring home to his readers a realization of its importance to human happiness and prosperity. Indeed, it is Prof. Sears's theme that man himself is, willy-nilly, an integral part of the living landscape he describes, and so cannot afford to disregard its laws. Though knowledge of science and technology has given him a measure of control over his environment, there is grave danger in the popular fallacy that science enables him to outwit Nature—thoughtless exploitation of natural resources during the past century has left

clear enough evidence of this. The pressure of the rapidly expanding human population makes it more urgent than ever before that we should be deeply concerned about conservation and the utilization of land to secure its highest potential for sustained productivity. The attendant need that ecological understanding should be "built into the wisdom of the human race" is really what provides the stimulus for writing this book.

Accordingly, Prof. Sears has written for the non-biologist, conveying, in his easy, friendly style, a breadth of vision and understanding that will commend the book widely. He illustrates his discussion with well-chosen examples drawn largely from plant biology. The biologist may feel a little disappointed that the stimulating introduction does not lead to something more detailed and precise. By following up some of the examples, the reviewer feels, the argument might have been made more forceful, yet at the same time this could upset the balance of the broad picture Prof. Sears has set out to give. There is a refreshingly wide perspective in the writing which must appeal alike to the general reader and those biologists, victims of extreme specialization, for whom plants and animals in their natural surroundings are unfamiliar and perhaps something of an anachronism.

In the teaching of biology in schools and colleges Prof. Sears urges priority for the out-of-doors as the proper laboratory in which to begin, so that the student may be "helped to see—really to see—grasses and trees, dogs and rabbits before we begin to talk to him of the marvellous self-replication of DNA or the relation of the Krebs cycle to bioenergetics". It is not that Prof. Sears is in any way seeking to put the clock back, but rather to restore perspective and a reasonable balance of emphasis, so that we may better understand the picture as a whole.

After introducing his theme in the first two chapters, and showing its relevance to problems of modern civilization, the author takes us back to the very beginning and reviews the narrow range of physical conditions, existing on this planet, which make life as we know it a possibility. He then sketches in some of the landmarks of biological thought, tracing the early stirrings of ecological ideas and the pioneer work which led to the emergence of ecology as a science in its own right. There follows a consideration of energy transformations and entropy, their bearing on life as seen in the individual's quest for a supply of energy and the circulation of energy and materials within a natural community; next some discussion of the classification of living things and the individual; then a short review of the contributions of water, rocks and soil to the living landscape. In the final two chapters, entitled "The Historical Factor" and "Reading The Landscape", the author rounds off what is a scholarly book, leaving the reader much to think about.

MAURICE ASHBY

## ELASTIN AND ELASTASE

### Elastolysis and Ageing

By David A. Hall. (A Monograph in the Bannerstone Division of American Lectures in Geriatrics and Gerontology.) Pp. xiii+160. (Springfield, Ill.: Charles C. Thomas, 1964.) 6.75 dollars.

THE fibrous proteins of connective tissue comprise more than 40 per cent of the total body protein in mammals, and it is not surprising that the structure of collagen and elastin and its change with age have been investigated extensively. Over the past ten years or more many chemists and physicists have found it more profitable to direct their attention to collagen and much is now known of its structure, but recently there has been a resurgence of interest in elastin. As detailed investigations reveal more precise information about its structure, no doubt attempts will be made to relate this new information to the behaviour of elastin-containing tissues *in vivo*,

particularly to changes accompanying ageing and the development of pathological conditions in the cardiovascular system. There is, however, a substantial gap between results of *in vitro* investigations on highly purified elastin and its behaviour in its very complex natural environment. Dr. Hall's book, therefore, appears at a very appropriate time, for it deals primarily with the interactions between elastic tissues and some of the agents they might be expected to encounter *in vivo*, in particular with enzymes of the elastase complex and their inhibitors.

Dr. Hall and his colleagues have been active in this field for a number of years, and *Elastolysis and Ageing* is, to a large extent, an account of their efforts. He has been led to the view that several of the features of vascular degeneration and atherosclerosis may be attributed to the interaction of the elastase enzyme system with elastic fibres, and here he attempts the onerous task of presenting a unified picture of these diverse phenomena.

The book is divided into four main sections. The first deals with the structure of elastic fibres and includes discussion of the properties of solubilized elastins and their possible relation to elastin fibrogenesis. Most of this section, however, is concerned with the evidence for a two-component structure of the elastic fibre, consisting of a protein core surrounded by a 'sheath' consisting of protein, polysaccharide and also probably lipid. Much of this evidence arises from experiments in which elastase was used as a 'structural probe', and the second, and largest, section describes the preparation and properties of this pancreatic enzyme. Hall, and more recently other workers, have recognized that this enzyme system contains two distinct enzymes which interact with elastic fibres—a proteolytic enzyme (elastoproteinase elastase) and a second enzyme which has a synergistic effect on the first and according to Hall and his colleagues is a lipoproteinase. The evidence for their existence and mode of action is discussed in detail together with the similarity of the lipoproteinase and the lipoproteinase of post-heparin clearing factor. The third section is devoted to the nature and mode of action of elastase inhibitors occurring in serum and elastic tissues.

Dr. Hall has drawn together all these facets of an extremely complicated situation into a unified picture in which the normal functioning of the blood vessel walls depends on a delicate balance of the effects of the several enzymes and inhibitors. The way in which this balance may be disturbed in ageing is indicated in the final chapter. In achieving this he has put forward several controversial hypotheses which attribute a key role to the mucoprotein-lipid complex of elastic fibres. This is regarded as being responsible for the binding of elastoproteinase to the fibres, for the binding of lipid and as a substrate for elastolipoproteinase. The need for caution in interpreting results obtained with highly purified elastin in terms of functional changes is thus emphasized.

The standard of presentation of the book is high, though there are a number of typographical errors, particularly in the description of some of the tables and figures, and some references have been omitted. G. C. WOOD

## ULTRASOUND IN SURGERY

### Ultrasound as a Diagnostic and Surgical Tool

Edited by Dr. Douglas Gordon. (Based on the International Symposium held at the Royal College of Surgeons, London, December 5th and 6th, 1962.) Pp. xii+413. (Edinburgh and London: E. and S. Livingstone, Ltd., 1964.) 63s. net.

THE task of editing a symposium is not an easy one, since the individual contributions do not necessarily come together as a complete account of the subject, and may occasionally represent facets, the growing points in the estimation of some but not necessarily of others. Dr.

Gordon has managed to preface this record of the first international symposium on "Ultrasound as a Diagnostic and Surgical Tool" by an eminently readable account of the general physics of this subject. Since the book is aimed at the clinical research worker, the text is couched in general terms and does not include much mathematical treatment, some of which is, however, included in an appendix. An account of the properties of ultrasound, and of its transmission and biological effects, precedes an account of crystals and transducers—all of which are simply and directly propounded. The chapter on generators, however, is much more technical and might with advantage also have been placed in an appendix. The chapter on measurement of ultrasonic power stresses the need for more uniform calibration scales before there can be a uniform assessment of results. There is a greater need for metering the intensity of ultrasound energy *in vivo* at the tissue level than is commonly allowed for in *in vitro* calibration. This trend, if established, would achieve greater selectivity in the production of biological lesions. The description of pulse echo technique is a particularly clear exposition of the subject.

The remainder of the book reflects the advanced work on this subject done in many different centres. Reflexion techniques are described in several chapters for the exploration of the heart and cranial cavity. It is of interest that ultrasonic methods have been explored not only for pre-operative diagnosis, but that, through the use of probes at operation, greater localization and detection of lesions is being achieved. For example, an intra-operative application for neurosurgical use is described by contributors from Japan, but might well also be utilized by the cardiac surgeons in examinations conducted within the heart. De Viegler reviews extra-cerebral methods of detecting the excavations and displacement effects of blood clot in subjects who have extra-cerebral haematomas. Dr. Gordon's own chapters cover tomography, measurement of the performance of diagnostic equipment, and a chapter on the other biological and medical uses of ultrasound. The most firmly established use of ultrasound is still in the treatment of Ménière's disease, and the chapters by Arslan of Padua and by the Bristol group state well the position in this subject in the hands of these experienced workers. Other chapters cover such diverse entities as ophthalmic ultrasonography, a means of producing neurological lesions in the experimental animal by focused ultrasound, and the statistical evaluation of such effects. Unfortunately, the Glasgow group contribution to the original symposium, concerning the obstetric and gynaecological uses of ultrasound, has not been included. This seems a strange omission at a time when an alternative means to the use of ionizing radiation is being sought for the examination of the female pelvis and its contents.

The book concludes with a useful glossary and bibliography, and is well indexed.

ADAM N. SMITH

## PSYCHOLOGY OF HUMAN LEARNING

### Categories of Human Learning

Edited by Arthur W. Melton. Pp. xvi + 356. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 68s.

THIS book presents the revised version of seven papers given at a symposium on human learning at Ann Arbor in 1962. The authors form a distinguished group—Grant on conditioning, Underwood on rote learning, Estes on probability learning, Postman on short-term memory and incidental learning, Kendler on concept learning, Fitts on skilled behaviour, and Gagné on problem solving—and had the purpose of the symposium

been simply to review these areas, it is likely that a useful, if unadventurous, volume would have been produced. To some extent this has been done, and the chapters by Estes and Postman, and to a lesser extent (because they were asked to cover a wider field) those by Fitts and Gagné, provide valuable surveys of the literature. But the editor had wider ambitions. "The theme of the symposium", he says, "is the interrelationship of different categories of human learning." The participants were asked to consider such questions as: Are all forms of human learning similar? Can comparable principles be discerned running through the different areas psychologists have investigated?

It is difficult to formulate such questions clearly; it should not be surprising therefore that it is even harder to answer them. Those participants who make the attempt come up with three classes of answer. The most popular solution is to argue that if the same variables have similar effects in different situations, then the learning processes involved must be similar. This argument is used by Kimble in his discussion of Grant's paper to suggest that since partial reinforcement has different effects in classical and instrumental conditioning, the two must be distinct; and by Postman in an attempt to show that short- and long-term forgetting are similar because both are due exclusively to interference effects (a suggestion which underestimates the significance of Sperry's work). Both Underwood and Estes point out that the argument is invalid, since quite apart from differences in learning processes, apparently similar operations might have different effects in different situations because "the operations are not comparable, because the effects of the variable are different in the two situations, because measuring units are not co-ordinate, or because other factors modify the effect".

Estes's answer is a theoretical one. He argues that if a single theory can handle the results of experiments in different areas, then the areas may be regarded as similar, and illustrates the argument by applying statistical theory of conditioning to experiments on probability learning. The claims he makes here for statistical learning theory are notably more moderate than those he has made in the past, but Anderson is still able to make some fundamental criticisms. These are both justified and well-intentioned: Estes's theories are too interesting to be allowed to be discredited by their failure to handle the complexity of probability learning experiments. Thus, although Estes may be ultimately right in suggesting a theoretical answer to the symposium's question, the specific example he uses is not particularly successful.

The third and most interesting suggestion is made by Underwood. His major thesis is that the search for common processes has been conducted at too superficial a level. "To point out that retroactive inhibition occurs in motor learning, in concept learning, and in verbal learning would seem to be of little value. We need to know the comparability of the mechanisms involved in producing the retroactive inhibition for the various tasks; we need to isolate the subphenomena to see if the total effects are compounded in the same way." It is not retroactive inhibition that is likely to appear in common in different areas (and if it does, this tells us little about the identity of the underlying mechanisms), but the more molecular processes the effects of which we lump together when we talk of retroactive inhibition.

Underwood's article is valuable both because he makes a serious attempt to answer what is surely an important and difficult question, and because the answer he proposes suggests one cause of its difficulty, namely the belief that "conditioning is the simplest form of learning", a belief which Kendler defends at length in this volume. Many objections have been raised in the past to the suggestion that all more complex forms of learning can be derived from conditioning; in the present context the implication to which one might take exception is that

conditioning itself is a simple process. This attitude has been responsible for the superficial level of analysis to which Underwood objects. If a more realistic account of the behaviour of humans in conditioning experiments were provided (if we could uncover the more detailed processes at work), then there might be a chance of showing these same processes at work in apparently more complex situations, and thus at last of integrating the various areas of human learning.

N. J. MACKINTOSH

## LABELLED COMPOUNDS

Proceedings of the Conference on Methods of Preparing and Storing Marked Molecules, Brussels, November 13-16, 1963

Pp. xxiii + 1359. (Brussels: Euratom, 1964. Available from Central Sales Office for Publications of the European Communities, 2 Place de Metz, Luxembourg; and Presses Académiques Européennes, 98 Chaussée de Charleroi, Brussels.) 1,000 Belgian francs.

THE preparation of labelled compounds is an absorbing activity for those relatively few people who undertake it professionally; but for the multitude of research workers who use radioactive tracer methods, procurement of a compound labelled specifically for the purpose at hand is a means to an end. If the right compound can be bought at reasonable cost, it usually will be. Nevertheless, the diversity of the requirements of tracer users is now so vast that no organized supply can possibly satisfy them fully, and research workers are necessarily left to their own devices to fulfil their more specialized needs. So producers and users of labelled compounds are related more closely than just as supplier and purchaser: they have many practical problems in common.

These mutual interests were the foundation of the conference on "Methods of Preparing and Storing Marked Molecules", which was the first international gathering on this topic. It was attended by 150 people of varying interests, coming from a dozen or more countries in addition to those of Euratom, who were the hosts and organizers. Clearly it was a most successful conference, which fulfilled a real need for direct personal communication. The *Proceedings*, which provide a full record of the conference, comprising seven general surveys and sixty-three original papers, should be equally valuable.

The established chemical and biological approaches to labelled compounds are reviewed competently by L. Pichat and J. R. Catch. Many of the other papers break fresh ground, by describing original synthetic methods for particular compounds or groups of them, and syntheses of some forty substances are recorded here for the first time.

The products described are almost exclusively those of biological interest—for example, the tropane alkaloids, chloramphenicol, the actinomycins, gibberellic acid, proteins and peptides; and they are predominantly labelled with carbon-14 or tritium. The papers reflect the present buoyant interest in tritium compounds as biological tracers and the trend towards still higher specific activity and specific chemical labelling with this isotope. There are rather few references to other labelled substances of technical interest outside the biological field.

A useful review by W. Herr of radiochemical methods for marking organic molecules emphasizes the merits and the difficulties of these methods. Other papers demonstrate the usefulness of the Wiltzsch method when it is applied critically to otherwise intractable problems of labelling, and also its practical limitations.

With the rapid growth of provision and use of radioactive labelled compounds, and the constant trend towards higher specific activities and more critical

standards of purity, better control of radiolytic decomposition during storage has become a matter of urgent practical importance. This first open discussion of the subject is therefore of special interest. Excellent reviews of the radiation chemistry of amino-acids and proteins are given by B. M. Tolbert and co-authors, and show the difficulty of relating the results of academic investigations to the stability of labelled compounds observed in practice. An empirical approach to this problem is generally the only one that is immediately useful, and accordingly the practical experience of several observers given in this and other papers is particularly valuable.

The book is excellently edited and printed. It is a large volume of more than 1,350 pages, but roughly half is taken up by English translations of the original texts in other languages. The translations are not always perfect, but they are most serviceable. The editorial staff of Euratom, the publishers and the conference organizers are to be congratulated on getting these proceedings on record less than a year after the event.

W. P. GROVE

## MATHEMATICAL ANALYSIS

An Introduction to Mathematical Analysis

By Prof. Robert A. Rankin. (International Series of Monographs on Pure and Applied Mathematics, Vol. 43.) Pp. xv + 607. (London and New York: Pergamon Press, 1963.) 80s. net.

REAL variable analysis is a standard part of the undergraduate course in most university departments of mathematics. It has been so for many decades, and it might be thought that the details of the subject, including method of treatment, are so standard and crystallized as to be almost lifeless. However, this is not the case, and a comparison of Prof. Rankin's *An Introduction to Mathematical Analysis* with some recent American and German books reveals how wide the discrepancy can be. Prof. Rankin's book is based on lecture courses given over many years at the Universities of Cambridge, Birmingham and Glasgow. It deals rigorously with subjects such as limits, continuity, differentiability, integration and convergence (of series and products), and presents what might be regarded as the traditional British approach to the subject. This approach is a gentle one for the student who has had a good grounding in school and first-year mathematics. It is reasonably down-to-earth and part of the philosophy is the provision at numerous points of suitable examples and exercises. In fact, Prof. Rankin writes in the preface as follows: "These exercises have a threefold object, to test understanding of the preceding theory, to provide practice in carrying out the techniques described, and to encourage imaginative thinking by requiring the student to provide his own examples and counter examples".

There can be no doubt that for the great majority of students the approach of this book is the right one. But how sharp is the contrast with, say, the recent book by Maak on *Introduction to Modern Calculus*. The latter is a beautifully written book, but the approach is highly sophisticated. Let us trace one aspect of the contrast, namely, the introduction of the trigonometric functions. Both authors use an analytical approach, with no reference to triangles. Maak, however, who directs much attention to sequences, introduces a particular sequence, the limit of which is the arctangent function. He then introduces inverse functions, and thus defines the tangent function as the inverse of the arctangent. After that the sine and cosine functions emerge in terms of the tangent function (of half the angle). Rankin, while remaining strictly analytical, makes very little use of sequences, and introduces the sine and cosine functions directly in terms of

the appropriate infinite series. His approach is both rigorous and practical; that of Maak, while attractive, is so polished and lengthy that none but the chosen few in the mathematical class can take it. In trying to reconcile these two books, perhaps the proper view is to regard Rankin's book as a prior text, and a very good text-book it is, and Maak's book as one of reference by those who already know the subject.

One half of Prof. R. A. Rankin's book is given to integration and to convergence and uniformity. A few words about the former may not be out of place. Two points of view are adopted. In the first, integration is defined as the reverse process to differentiation, and this approach leads to the standard results of the theory quite quickly. In the second the Riemann-Stieltjes integral and the Riemann integral are introduced, the theory being based largely on the properties of interval functions and dissections that are studied previously. Once again the sound practical approach to the subject is evident.

Prof. Rankin's book is a first-class text for undergraduate classes. Not only are numerous exercises provided but also hints for the solutions of many of these are given. It is a gentle text and will form a most valuable adjunct to a course of lectures on the subject.

L. S. GODDARD

## STRUCTURE AND MEANING

### Structural Anthropology

By Dr. Claude Lévi-Strauss. Translated from the French by Claire Jacobson and B. G. Schoepf. Pp. xvi+410. (New York and London: Basic Books, Inc., 1963.) 52s. 6d.

ANY professional teacher of social anthropology (say, any one of the 200 or so members of the Association of Social Anthropologists) must be competent to write a conventional introduction to the subject, that is, to the work of other people, for if he could not so order the elementary instruction which he provides he should not occupy a university position. To receive *Structural Anthropology*, therefore, as yet one more text-book would be to encourage no special expectation. Prof. Lévi-Strauss, by contrast, is not only one of the extremely few scholars of sufficient distinction to be able to say, without presumption, what social anthropology is about; but he has also actually demonstrated, by numerous analytical articles and monographs, that he is pre-eminently worth listening to. He does not just talk about the subject, he works; he does not simply practise social anthropology, he makes exciting and original contributions to it.

Yet this collection of some of his papers, although the nearest thing so far published to a representative introduction to social anthropology, nevertheless shows that a text-book of the subject is not possible. It has, to begin with, no distinctive subject-matter, and it possesses no singular method of analysis. Lévi-Strauss demonstrates the former point by writing about a wide range of disparate topics such as sentiments, dual organization, sorcery, myth, symbolism, dialectics, and split representation, taken from a variety of both great and minor civilizations; and he makes the second by constant references to history, linguistics, communications theory, and physics. What is it, then, that he and the discipline of which he is the foremost theoretical proponent have to offer to human understanding?

The most concise response is that social anthropology is the structural analysis of meaning. Its focal concerns are social categories, relations, and values; its characteristic objects of examination are symbols. The source of the special authority of the social anthropologist in this extensive and general field of investigation is the universal scale against which he pursues his enquiries, so that when he tries to construct general propositions (as, of course,

do historians or economists) he alone may properly aim at complete generality within the territorial and temporal limits of mankind. Thus Lévi-Strauss deals, in one essay, with material and with periods as greatly dispersed as China in the first to second millennia B.C., the Amur region in the prehistoric era, Brazil in the twentieth century, and New Zealand in the fourteenth to eighteenth centuries. The social anthropologist cannot be a polymath to the extent of possessing a scholarly command of all that is known about every area and period, but the breadth of his comparisons and the abstract nature of his discipline as a general theory of relations permit him, nevertheless, to advance novel and empirical considerations.

*A priori*, it would seem unlikely that this result might be possible, but Prof. Lévi-Strauss is superbly capable of demonstrating that it is. He does so in the main not by concentration on substantive cultural particulars but by analysis in such relational terms as opposition, reciprocity, and homology, and it is through the structural models thus constructed that he is able to encompass such a mass of apparently incomparable evidence. How he does so is not a matter for report but for examination, and anybody who thinks such an enterprise worthy of attention should learn much from reading this volume. But even Lévi-Strauss cannot be taken as an exact exemplar in all respects, and the most prominent ground for demur concerns the relationship of his own work to linguistics, the subject to which he so frequently has recourse in his methodological observations. He makes many professions of illumination yielded by linguistics, and generously concedes priority to it as a field of more advanced structural analysis; but it is a question whether social anthropology has ever profited in one clear respect from the example of that admirable discipline. The parallels of concept and method to which Lévi-Strauss alludes are indeed noteworthy, but it is arguable that they are no more than parallels, for the principles implicit in his work are readily discernible in Dumézil also, in Hocart and in Rivers, and of course in Mauss and Hertz and Durkheim. The structuralist approach which these scholars have used, in a long and continuing tradition of ideas, owes nothing historically and particularly to linguistics; nor is there to be found in linguistics to-day, for example in the algebraic tautologies of the so-called "componential analysis of kinship", any more immediate or useful effect. We should instead take it, therefore, that Lévi-Strauss has merely found in the terminology of linguistics a technical idiom which appeals to him, rather as Dr. E. R. Leach (Lévi-Strauss's counterpart in Britain) has found it convenient to make a similar comparison with topology. This view is not merely a suggested qualification to be kept in mind when reading Lévi-Strauss's papers, but, if accepted, it has the result of at once making his thought more directly accessible to understanding, and placing him in a recognized tradition proper to his discipline.

What this discipline is, to return, may be illustrated—not catalogued—by the papers in *Structural Anthropology*. They are divided into five sections: language and kinship; social organization; myth and religion; art; and problems of method and teaching. The seventeen articles were originally published, all but four in French, between the years 1945–56 (the collection could be marvellously amplified with other papers published since), and have been translated into an exact and fluent English by Claire Jacobson, with the collaboration of Brooke Grundfest Schoepf. A random check reveals small uncertainties, or even a misrendering such as "generalized reciprocity" for the key term "*échange généralisé*", but in general the translation is excellently worthy of the author. There is a full bibliography and a good index. The volume is most handsomely produced, and it is only to be regretted that the American publishers (unlike the original French) should have found it expedient to put the footnotes exasperatingly at the end of each article instead of where they belong.

R. NEEDHAM

### Behaviour of Electrons in Atoms

Structure, Spectra, and Photochemistry of Atoms. By Dr. Robin M. Hochstrasser. (The General Chemistry Monograph Series.) Pp. xii+162. (New York and Amsterdam: W. A. Benjamin, Inc., 1964.) 4.50 dollars.

A STUDENT of chemistry needs to know, at the very start of a university career, something about atomic structure and atomic spectra. However, because the interactions between electrons are complex and intricate, it is extremely difficult to give an account which is both honest and at the same time easily intelligible to the newcomer. Moreover, it is to be hoped that such an elementary description will not only be intelligible, but will also give the student some feeling and understanding for the factors that govern the energy and other properties of atomic systems.

Prof. Hochstrasser has tackled this problem in a new and interesting little book of 162 pages. The presentation is qualitative in character and does not attempt to derive mathematically the various expressions that are presented in the text. The figures are extremely good, and the use that has been made of colour in the energy level diagrams adds greatly to their intelligibility. The material is well set out and clearly written, and the summaries at the end of each chapter are most helpful. There are also some good problems.

Most of the book is very successful, but it is somewhat doubtful whether the section in the neighbourhood of page 50 will give the young student any real feeling for orbitals and the corresponding probabilities. The same is also true in respect of the energies of atomic systems, which are dealt with in Chapter 4. However, in this chapter some features are brought out more successfully than elsewhere; Fig. 4-5 is a helpful one. With regard to energies, Fig. 5-2 is wrong because all the levels for the lithium atom should be below those for the hydrogen atom which have the same principal quantum number. In Table 6-1 it would have been helpful if an energy or frequency scale had been given. Chapter 7 is very interesting, but it is doubtful whether Chapter 9 was worth including.

The author started by linking his description closely with experimental data. In the middle of the book he unfortunately departed from this approach to a considerable extent but returned to it strongly in the last few chapters. He can certainly be congratulated on providing a useful little book which will help new chemistry students in a subject which they frequently find difficult. However, they will ultimately need to carry their knowledge further.

J. W. LINNETT

### Stress Waves in Anelastic Solids

Edited by Herbert Kolsky and William Prager. (International Union of Theoretical and Applied Mechanics Symposium, held at Brown University, Providence, R.I., April 3-5, 1963.) Pp. xi+342. (Berlin, Göttingen and Heidelberg: Springer-Verlag, 1964.) 67.50 D.M.

STRESS wave problems are among the most important, technologically, of the problems connected with deformable media. They may not be the centre of interest. Steady-state problems are likely to take pride of place so long as any important ones remain unsolved, and in recent years experiments at hypervelocities and questions about implosion have proved fascinating. But stress waves have never been far from the centre of interest, and during the past ten years solutions have been obtained to many wave problems in spite of theoretical and experimental difficulties.

The contents of *Stress Waves in Anelastic Solids* are the invited papers at a symposium attended by many, if not all, the experts in this field. That it should be solely concerned with anelastic solids and large strains emphasizes both the advanced stage of the theory for elastic

materials and the inadequacy of that theory when there is a concentration of stress. Even the paper by Goldschmidt, at the end, giving reproducible data for such a difficult material as rock, is concerned with the dynamic as well as the static characteristics.

The two main problems in the field are the discovery of the laws of flow with large and variable strains, and the analysis of the wave patterns which arise. It is clear that steady advances are being made in both problems, but it is also clear from the papers on shock waves and those on plastic waves that the laws of flow yet known are only just adequate to correlate experiment and theory. An excellent review by Hopkins on strain-rate effects is followed by a paper by Hunter and Johnson, who analyse the propagation of small plastic vibrations along a bar, and show that the dispersion due to the finite cross-section is so appreciable at low frequencies that it could explain the results without introducing any strain-rate effects.

There are a number of papers analysing the structure of the wave pattern and its development with time. There are two on spherical and plane shocks, one on transient wave and fracture, and many dealing with waves of finite amplitude and their decay. The more interesting papers are distinguished by a final selection containing conclusions. There is a challenge here to theorists, as well as experimenters, to solve problems even more difficult than those connected with shock waves in aerodynamics. Even if the properties of the material are known, and symmetrical arrangements are chosen to avoid awkward reflexions at boundaries, these wave problems in solids remain confused owing to the internal discontinuities due to change of structure, and the associated dispersion and anisotropy.

Meanwhile, practical problems must be solved and theoretical calculations continue. There are some excellent mathematical papers on plastic waves, including one on anelastic ropes, and several on viscoelastic solids, which deserve a more complete discussion than can be given here. This is a collection of individual papers which gain by being published together.

G. J. KYNCH

### Numerical Methods

By Dr. Ben Noble. Vol. 2: Differences, Integration and Differential Equations. (University Mathematical Texts.) Pp. viii+157-372. (Edinburgh and London: Oliver and Boyd, Ltd.; New York: Interscience Publishers, Inc., 1964.) 12s. 6d.

THE first volume of Noble's book dealt with iterative methods for solving algebraic equations, programming, linear equations and matrix methods. In this second part, the relevant parts of the calculus of finite differences are expounded and then applied to the interpolation, differentiation and integration of tabular functions. Then there is a long chapter on ordinary differential equations, with accounts of iterative methods (Runge-Kutta), predictor-corrector methods (Adams-Bashforth, Milne), and deferred-corrector (central difference) methods. In the final chapter, we have a good if brief introduction to finite-difference and relaxation methods for partial differential equations of the second order in two space variables. But the volume is no mere epitome of formal techniques; much attention is paid to the choice of appropriate practical methods, to error estimation and to the often subtle question of stability. There is in fact a surprising amount of information packed into this small book, for the author shows a happy skill in combining brevity with clarity. Fifty years ago, it was difficult to find a text on numerical analysis; to-day, the difficulty is one of choice out of a very large number, but the novice will get as good a view of the domain and its major routes from Noble's book as he can find anywhere. He will not get much direct help for further reading, but the author very wisely recommends for this purpose the good bibliography in *Modern Computing Methods* (H.M.S.O.).

T. A. A. BROADBENT

## SIR HENRY TIZARD (1885–1959)\*

By PROF. R. V. JONES, C.B., C.B.E.

Department of Natural Philosophy, University of Aberdeen

SIR HENRY TIZARD'S work and, above all, his part in our survival in 1940 have been the subject of many memoirs since his death in 1959. The biography commissioned by his family and written by Ronald Clark will shortly appear. This first Memorial Lecture of the Royal Aeronautical Society thus occurs when a full record of Tizard's life is about to be made available, and there is therefore little point in the plain reiteration of a condensed biography. Future Memorial Lecturers, as they inevitably grow more remote from personal contact with Tizard, may well choose to describe the advances of the future in those fields to which Tizard himself so notably contributed: science, defence, education and government. My purpose in this first Memorial Lecture is therefore to build a bridge between biography and those future fields in which Tizard's example, although unlikely to be excelled, will be emulated and extended.

As for my qualifications to do so, there are certainly men who knew Tizard more closely than I did. They were more nearly his contemporaries. But I was fortunate in my generation in being brought into his orbit at an early stage; and his effect on my own career was profound. When I first met him in 1937, he was at the height of his work and I was, at twenty-six, half his age. Age or youth was, however, no barrier with Tizard—he could talk easily with either; he was always keen to know what the young men thought—and he was always ready to give them the benefit of his experience, and to stimulate them with challenges. This was to be my good fortune over a period of twenty-two years.

## Westminster, Oxford and Berlin

This period, however, covered only the last third of Tizard's life, and I cannot claim first-hand knowledge of his earlier life except for a few chance sidelights that arose from comments that he made to me. Instead, I have to depend heavily on Sir William Farren's biographical memoir for the Royal Society and the biography that Mr. Clark has very kindly allowed me to see. From these sources you can find that the Tizard family came as Huguenot refugees to Dorset, with a tradition of connexion with the sea. Over the centuries they are said to have become "more English than the English". Henry Tizard once remarked, "With a name like mine, you have to be!" His father, Captain T. H. Tizard of the Royal Navy, was assistant hydrographer of the Admiralty, and it was taken for granted that the son would in due course follow into the Navy. In the summer of 1898, however, when Henry was nearly thirteen, a fly flew into his left eye; when he closed this eye he found that he could no longer see—and thus realized that his right eye had a blind patch. This incident changed his life, for his prospect of entering the Navy was shattered. Recovering with characteristic resilience, he won an Exhibition to Westminster School in 1899; and from there, feeling in the meantime the appeal of science, he won a Demysip in chemistry at Magdalen College, Oxford. He was thus set on a career in natural science. His 'First' in chemistry was backed up by another 'First' in Mathematical Moderations; and having run the gauntlet of a classical education,

and with a naval background that showed itself academically in a study of the works of Mahan, Tizard was admirably poised for the contributions that he was to make.

At first, it seemed that these might primarily lie in pure research. After his degree at Magdalen in 1908, he went to Berlin to work under Nernst. There he met Frederick Lindemann, working in the same laboratory. The story of their subsequent friendship and quarrel is near high tragedy. Much has been said and written about it, and I shall have little to add here, beyond saying that Mr. Clark has done a service in setting out the facts with an impartiality that Tizard himself would have applauded. The quarrel cannot be ignored, although its importance can be exaggerated; it is not a subject for vindictive anecdote, but it is a study in human relations between two men, each greater than most of us, who, with some astonishing similarities in experience and outlook, nevertheless became antagonized at the crisis of their country's survival. As such, it may with value be studied by any of us who are concerned with science and Government, not with the view of deciding who was right and who was wrong, but as a background against which to guide our own conduct should we be faced with our own crises. That the quarrel was between men of science was—contrary to outside opinion—immaterial. It could have arisen between two men in any field, and it is perhaps the common delusion that men of science are above emotion that has made the story such an occasion for popular remark.

At the time that Tizard met Lindemann, their different personalities were obvious, but their similarities were substantial. Both came from refugee families, both were men of science; their births coincided within a few months, and they each had defective vision in one eye. At a time when such views were unfashionable, both believed that science merited a fuller place in education and that good technology was a foundation of national well-being. Both were men of high courage, and in the War that followed in 1914 both flew aeroplanes with conspicuous understanding and skill.

In the years between 1909, when Tizard returned from Berlin to Oxford, and the outbreak of the First World War, he worked first on the sensitivity of chemical indicators, and later on electricity in gases. He was elected to a fellowship of Oriel College, Oxford, in 1911, and it appeared that a pleasant life stretched indefinitely before him. He afterwards told how he was contemplating this happy prospect over the comforts of hot anchovy toast and tea beside a blazing fire in his rooms in college after an afternoon walk: "What a lucky fellow I am—everything I want!", he thought—and immediately followed by "I shall stagnate—I must get out of this at once!"

A fortunate vacancy on the party of the British Association for the Advancement of Science going to Australia in 1914 was offered to Tizard at the last moment. This he afterwards described as his "greatest piece of good luck", and he sailed on July 1, 1914, in company with many eminent men of science. In particular, he met Rutherford, and formed a friendship which lasted until Rutherford's death, and which he most happily described in a notable broadcast of 1945. By the time the party reached

\* First Tizard Memorial Lecture of the Royal Aeronautical Society, delivered on October 28, 1964, at Boscombe Down.

Australia the War had broken out, and in October he returned to England with H. G.-J. Moseley, then aged twenty-seven, who had already "called the roll" of the chemical elements with his X-ray spectra; Moseley was killed while serving as a signals officer at Gallipoli in 1915.

### Bombsights and Test Flying in the First World War

Tizard joined the Royal Garrison Artillery at Portsmouth in November 1914 and was allocated to anti-aircraft gunnery; but, finding that he had too little to do, he secured a transfer in July 1915 to the Royal Flying Corps at Upavon as a second lieutenant and assistant equipment officer. In the meantime, in April 1915, he married Miss Kathleen Wilson, whom he had met five years before at Oxford. Robert Bourdillon was their best man, and it was the work of Bourdillon and G. M. B. Dobson on bombs and bombsights that attracted Tizard to Upavon. But again he encountered frustration: aeronautical research in Britain was being conducted by three separate bodies. The Royal Aircraft Establishment, then at Farnborough, had originated at Woolwich in 1878 as the War Office Balloon Equipment Store; the Advisory Committee on Aeronautics (now the Aeronautical Research Council) directed the Aerodynamics Department of the National Physical Laboratory; and in addition there was the Experimental Flight of the Central Flying School at Upavon.

The primitive state of knowledge and the thoroughly experimental approach of the Central Flying School are illustrated in a story afterwards told by Tizard: "Some young officer argued one day in the Mess, that as the resistance to motion got greater the further anything dropped under gravity (which is true) it followed that if you dropped an egg from a sufficient height, say 3,000 feet, it would not break when it hit the ground. This outrageous statement was received with hilarity by the young scientists present, but the Commandant was not convinced by their scepticism and decided to make the experiment".

A pilot was duly ordered to take a *Maurice Farman* up and drop the eggs one by one. Tizard went on:

"We all waited patiently while the machine climbed laboriously to this dizzy height, but no one saw anything dropped. When the pilot came down he said that he had dropped all the eggs; so a search was made for them. No trace of them was found and so the question had to remain open".

Tizard himself worked on a bombsight, the first the Royal Air Force ever had. He devised a photographic method of recording bombing runs from the ground, and his observations led him to suspect that sighting errors were in fact much less than flying errors. "I then came to the conclusion", he wrote, "that it would be difficult for any scientific man to do really important relevant work unless he himself learnt to fly." An argument with the War Office followed. The Central Flying School was held to train operational officers: Tizard was not an operational officer, and so he could not be trained. As a compromise, it was agreed that Tizard could be trained if his training took place on days which were too bad for training operational officers. And so he learnt to fly.

Many of the details of this period of Tizard's career can be read in Ronald Clark's biography—they will ring true to anyone who has worked in that fascinating region between science and the services, characterized by mutual admiration for each other's achievements and amusement at each other's peccadilloes. In this atmosphere, in which the enthusiasm of the pioneer was enhanced by the urgency of war, Tizard gained that deep understanding of the interplay of the scientist and the serving officer that was going to be so valuable in 1940.

The frustration experienced by Tizard arose partly from the fact that it was not easy to test experimental

armaments at a training aerodrome. Fortunately the situation changed sharply with the appointment of Bertram Hopkinson, professor of engineering at Cambridge as Director of Aeronautical Equipment in the War Office. Hopkinson quickly realized the difficulties, and moved the armament work to Orford Ness in June 1916, and the remainder of the Experimental Flight, now renamed the Testing Squadron, from Upavon to Martlesham at the end of 1916. Tizard was appointed as Captain in Charge of Experiments at Martlesham early in 1917. His work was concerned with the development of test flying, and as quickly as March 1917 he read a characteristic paper on "Methods of Measuring Aircraft Performance" before the Society. In it he described the system he had introduced in the Testing Squadron for accurately establishing the performance of an aircraft despite variations of altitude and of weather. He had great faith in the value of direct observations by the pilot, and relied on recording instruments only as a check on these observations. The quality of the pilot's work was, according to him, what mattered more than anything else:

"In the end the accuracy of the results really depends upon the flier, who must be prepared to experience a care and patience unnecessary in ordinary flying. Get careful fliers whose judgement and reliability you can trust, and your task is comparatively easy; get careless fliers and it is impossible".

Tizard had placed his stamp on the character of test flying. Before him, skill and bravery were the attributes sought in test pilots; after him, they had in addition to be patient, objective observers.

On one of his own test flights in a *Sopwith Camel* in July 1917, a formation of *Gothas* was reported to be making for London. Tizard, whose plane had untested guns succeeded in intercepting the formation, twenty strong at 17,000 ft. His guns jammed after less than 100 rounds, and so he shadowed the formation taking note of its aerodynamic performance.

Towards the end of the year, Bertram Hopkinson invited him to go to the Ministry of Munitions as his deputy. After Hopkinson was killed in August 1918, Tizard took over in his stead, finishing the War as a lieutenant-colonel and being awarded the Air Force Cross in recognition of his test flying. He returned to Oxford and became reader in thermodynamics in February 1920.

### Aircraft Fuels

Among the interests that he carried back to Oxford as a result of his war experience was that of aircraft fuel. In 1917 special aircraft fuel was running short because of sinkings by German submarines. This oil came from Pennsylvania and consisted almost entirely of aliphatic hydrocarbons. Tizard decided that tests should be made at Martlesham of diluting the Pennsylvania fuel with benzol from gasworks. This mixture turned out to be even better for aircraft engines than the Pennsylvania fuel alone. While the benzene in the mixture tended to freeze out at low temperatures, the other aromatic contents in the benzol did not. This work brought Tizard into contact with H. Ricardo, who invited his co-operation in a major programme of research for the Asiatic Petroleum Company. Tizard brought in David Pye, and they worked between Oxford and Ricardo's laboratory in Shoreham. They confirmed that the incidence of detonation was the most important single factor limiting the performance of the petrol engine, and Tizard suggested that this factor should be expressed in terms of a 'Toluene Number', which would be the proportion of toluene (the least prone of any known hydrocarbon to detonate) that had to be added to heptane (the worst) to match the detonation quality of the fuel under examination. Some years afterwards the Americans replaced toluene by iso-octane, resulting in the standard 'Octane Number' definition of the anti-knock properties of a fuel.

# The Department of Scientific and Industrial Research and Aeronautical Research

While this work was going on, Tizard received in 1920 an invitation from Sir Frank Heath to join him at the Department of Scientific and Industrial Research, then four years old. Such a change of career involved much thought. His correspondence with Heath shows that he realized very well the difficulties that the new Department would find in making its way, largely because it had been set up at a relatively late phase in the development of Britain. For lack of much central thinking about research, even more so in technology than in science, a number of independent organizations had been set up to deal with specialized aspects of applied research, and it was not clear, for example (and the example was Tizard's), what the part of the Department of Scientific and Industrial Research would be in co-ordinating aeronautical research, which was already under way at Farnborough and the National Physical Laboratory. We are still not free from the difficulties that Tizard foresaw, although, with the deliberations of the Trend Committee, some of them are beginning to be faced.

There were several reasons that determined Tizard in coming to the conclusion that he ought to leave Oxford and take up the burden of the Department of Scientific and Industrial Research. Among these was his realistic assessment of his prospects in pure science, where he had lost five of his most creative years in the War, and where younger men of great ability were coming up. The more important reason was, as he recorded: "My war experiences had taught me the value, and interest, of the application of science. It was a neglected field in England".

Tizard's work as Assistant Secretary of the Department of Scientific and Industrial Research was control "of the group of Boards and Committees entrusted with the co-ordination of research for the fighting services". This represented an early attempt to straighten out the tangle of research around the Armed Forces, and if anyone could have done it, it was surely Tizard. But the task, difficult even under the urgency of war, was impossible in peacetime. Too many independent bodies were individually too well set to be merged into effective combination. The Germans faced this same problem later when the clandestine research organizations set up before 1933 came into the open; because they were clandestine they had had to be small, and even a single Service like the *Luftwaffe* had several of them. And when they became overt, they were individually too strong to be welded into a really effective organization. Despite these lessons, we are still in the same kind of difficulty in Britain to-day. There may not be a complete solution: one mammoth research organization for all problems, both military and civil, is not the answer, nor is a large number of *ad hoc* and uncoordinated research institutes. Somewhere between may lie the optimum compromise.

Anyhow, by 1927, Tizard had seen that the boards and committees were not really effective, and they were all dissolved except for the Radio Research Board. In the meantime his interest in aeronautics had remained; he had been a member of the Glazebrook Committee on Education and Research in Aeronautics in 1918 and 1919 which had recommended that there should be a Board of Aeronautics run jointly by the Air Ministry and the Department of Scientific and Industrial Research. The Service did not like this proposal, and it was not implemented. Tizard himself in 1924 suggested to the Air Member for Supply and Research (Sir John Salmond) that the actions should be separated at director level, and a director of scientific research appointed to take charge of the research activities of the Air Ministry. This suggestion was accepted by Salmond and backed by Tizard, who had been consulted. They were clear out who the first director of scientific research should

be: Tizard. However, Tizard refused the post because, to judge by the salary offered, the Air Ministry was not recognizing its status adequately; finally, the Treasury was persuaded to make Tizard personally a special offer, but he rejected it because he thought that it ought not to be personal, and that it would be unfair to another director in a comparable post if Tizard were to be paid more than he was. After some delay, H. E. Wimperis was appointed instead.

At the time when these negotiations were going on, Tizard delivered the Wilbur Wright Lecture to the Royal Aeronautical Society. The text of it appears in the *Journal of the Royal Aeronautical Society* for 1924, and the immediately following paper is that of his inaugural address as chairman of the Society later in the year. He chose as his title "Commonsense and Aeronautics", and in it he gave the new Directorate of Scientific Research the benefit of the doubt that he privately felt about the scope that it would be given by the Air Council:

"We look for the closest co-operation between the executive and the scientific branches; between, in short, the user and producer. The war showed us the value of that; but we seem to have been forgetting the lesson. Our little aeronautical world has tended to be divided into so-called scientists (a small, slightly troublesome, and wholly incomprehensible sect) and practical men (who do the work). Placed on close but parallel lines, they only meet at infinity. Four years of experience on the Aeronautical Research Committee has taught me the danger of this; but we hope that the new organization will avoid it".

The 'commonsense' of the title Tizard explained as that of "the intelligent thoughts of the ordinary man" and he ranged over civil as well as military aeronautics, making a powerful plea for reliability and safety as the foundation of a thriving civil aviation industry. The address is well worth reading in entirety to-day. Let me quote a little to convey something of its spirit and foresight:

"One often gets the impression from debates in Parliament, and from articles in the press, that military research is believed to result solely in the evolution of new methods of destruction, and to have no real value in itself. Nothing, surely, could be further from the truth. . . . In scores of ways, direct and indirect, the results of research undertaken primarily to meet Service requirements are continually filtering through to, and benefiting, the industries of the country. . . . Few, if any, industrial organizations in this country could afford to carry out the kind of work that is pursued in the Services experimental establishments, even if they were convinced of its value; and yet it is just this kind of work that leads in the long run to important industrial advances. . . . There is only one danger that I see in this instance of the value of scientific work. It is that the scientific worker may continue to be regarded, as he undoubtedly has been in the past, as a peculiar being, to be segregated from his fellow men and left to the evolutions of his inner consciousness. . . . But most of us, it must be admitted, need the inspiration of practical aims to call forth our best work. In applied aeronautical research there is room for everybody. A vast amount of important work waiting to be done needs no deep scientific knowledge; scientific method and a logical and unprejudiced mind will carry one far. There are officers in the executive branch of the Royal Air Force, the value of whose judgement, criticism and experimental skill is gratefully recognized by the scientific world. To such a one, the Society has awarded its Silver Medal tonight".

Incidentally, the recipient of the medal was Squadron-Leader R. M. Hill who, as Air Chief Marshal Sir Roderick Hill, was later to follow Tizard in the Rectorship of the Imperial College of Science and Technology.

In 1927, Tizard succeeded Heath as Permanent Secretary of the Department of Scientific and Industrial Research; but in 1929, in a move that had something of accident

about it, he left the Department to become Rector of the Imperial College of Science and Technology. There was, of course, nothing accidental about his fitness for the new post: his natural interests in technology and in education, coupled with his administrative experience, qualified him admirably. And while his new duties absorbed much of his energy, he was well able to continue national work as a now independent member of Committees and Boards. In a special place among these was the Aeronautical Research Committee, of which Tizard had been a member, in one capacity or another, since 1920. Tizard was chairman of the Engine Sub-Committee. Against protests he insisted on a policy of testing all new Service engines on fuels of higher octane rating than those then generally available: he argued that under the stimulus of war such fuels would be produced, and therefore that the engines should be designed to operate at higher pressures and so take advantage of them. As a result of this policy, when improved fuels were produced in 1940, our existing engines could be used with confidence. This example seems to me to be 'vintage Tizard', showing his faith and foresight at their best—not so extravagant as to make it impossible to carry others with him, but showing an extra anticipation that others lacked.

### The Jet Engine

Tizard was faced on the Engine Sub-Committee with a basic invention of outstanding importance—the jet engine. In 1926 A. A. Griffith put up a paper on the aerodynamic theory of turbine design, with the view of an axial-flow turbine driving a propeller, and Tizard proposed that the theory and its implications should be examined at Farnborough. As a result, an experimental rig was set up, and Tizard presided over a panel in 1930 to consider the results. Although Tizard himself felt that experiments should be pressed further, carrying the panel with him on this point, he agreed with the other members of the panel that there was as yet not enough ground for large-scale financial support; misgivings had been expressed about the abilities of known materials to withstand the operating conditions. There is some evidence to suggest that Griffith was discouraged by this equivocal verdict, and his work at Farnborough thereby lost its impetus. In the meantime, independent of all this, F. W. Whittle was working on his own ideas of a jet engine, and met Tizard at the Cambridge University Air Squadron Dinner in 1936. Tizard, after some months of thought, was convinced; and by February 1937 had carried the Engine Sub-Committee with him to the extent of recommending that the Air Ministry should explore the possibility of supporting Whittle's development. In retrospect, this appears leisurely progress, but it had had to be made against substantial opposition; and Sir Frank Whittle has said of this vital stage "Our best friend was Sir Henry Tizard". The subsequent history of the engine will be well known to many members of this Society, and can be read in Sir Frank Whittle's book *Jet*. He records how Tizard saw a successful demonstration run on the experimental engine in January 1940 and commented: "A demonstration which does not break down in my presence is a production job".

### The Committee for the Scientific Survey of Air Defence

In the early years of Tizard's Rectorship of the Imperial College of Science and Technology, it became increasingly obvious that the policy of Nazi Germany was very likely, sooner or later, to lead to war, and that Great Britain would have to defend herself against the attack of the German Air Force. As a result, despite Mr. S. Baldwin's counsel of despair in 1932, that "the bomber will always get through", a renewed scientific appraisal of the problems of air defence would almost certainly take place in one form or another—the national need was far too strong

and too widely felt to be ignored. This situation brought about two trains of events that were between them to give Tizard the opportunity for his greatest work, and to give him his greatest source of pain. In the Air Ministry A. P. Rowe, scientific assistant to H. E. Wimperis, began an informal survey of the air defence problem; this led Wimperis to propose that a committee should be formed for the scientific survey of air defence, and that Tizard should be chairman. Tizard was formally invited on December 12, 1934, the other independent members being Prof. A. V. Hill and Prof. P. M. S. Blackett.

While these steps were being taken, and perhaps even before, Prof. Lindemann in Oxford had been pressing with Mr. Winston Churchill, for a scientific investigation of the air defence problem to be made, most of the pressure being applied at the political level, and particularly to Mr. R. MacDonald, then Prime Minister, and Mr. Baldwin. When Lindemann discovered that in the meantime the Air Ministry had formed its own committee under Tizard, there was obviously scope for misunderstanding. Lindemann particularly wanted a committee independent of the Air Ministry, which he blamed for having given Baldwin such poor counsel in 1932, and had therefore suggested that the new body should be a sub-committee of the Committee of Imperial Defence. It looked to him as though the Air Ministry had brought Tizard in as part of a conspiracy to frustrate a truly independent investigation. There is no evidence whatever that this was in fact the case, but the unfortunate suspicion may well have coloured Lindemann's attitude. I do not propose here to recount the subsequent story of the differences, which have been described in varying ways by—among others—Prof. Blackett, Sir Charles Snow and myself. Lindemann's side of the picture has already been given by Lord Birkenhead in his biography, *The Prof. in Two Worlds*, and a thoroughly objective account will shortly be available in Mr. Clark's book. The fact to be remarked here is that despite the complications caused by the existence of two bodies (for the Committee of Imperial Defence did later form a sub-committee to deal with air defence, and appointed Tizard as a member), and despite the dislocation of the Tizard Committee's discussions caused by the attitude taken up by Lindemann, this latter Committee proved to be one of the most important and successful in our history.

There is absolutely no doubt that Tizard was the best possible choice as chairman. He had all the desirable experience, both as a scientist and as a serving officer; he had had acute experience of armament development; he had inherent faith in technology; and he was an understanding and skilful chairman. The difficulties with Lindemann apart, he was fortunate in his opportunity. He had on the one side a considerable potential of scientific knowledge and enthusiasm to draw on, both in the Government research establishments and in the universities; and on the other side he had a cadre of serving officers in the Royal Air Force who realized that in the difficult problem of air defence their Service was 'up against it' and who were therefore particularly ready to try out any device that might offer promise. As the ultimate stroke of good fortune, Watson Watt had produced, just as the Tizard Committee met for the first time on January 28, 1935, the idea that it might be possible to detect an aircraft by the energy that it reflected from a radio-transmitter or the ground.

### Radar and the Biggin Hill Trials

It is one thing to be presented with good fortune; but to take full advantage of it, it is necessary to have the appropriate background and to visualize the possibilities. Tizard had both these qualities in high degree, and in the next four years they were applied with brilliant devotion to the threatening problem of German air attack. He rightly foresaw that attack by day was the major threat

and the original radar system was built up to deal with this threat. It was also generally realized that, although the limited accuracy of this system would be sufficient for daylight operations, it would not by itself be adequate to solve the problem of putting a night-fighter into the necessary visual contact with a bomber in darkness. Tizard himself appears to have been the first to suggest that a small radar set might be made to go into a night-fighter, but for some time it was not clear whether such a set would fulfil its aim, since there was difficulty in making short enough pulses to give the necessary minimum range. In the meantime, the development of the original Chain Home System was proceeding, and it was an almost fantastic achievement by Watson Watt and his team that they should have converted the fitful radar sets of 1936 into a reliable operational system by 1939, especially at a time when 'Made in England' was no longer a synonym for reliability.

Tizard's part in all this was to have the judgement and faith to convince the Government to spend the necessary money. In retrospect, this may not appear to be a particular achievement; but in 1935 and 1936, with many of the technical uncertainties still in prospect, especially those of converting an unreliable laboratory demonstration into a reliable system that could be handled by the Service, it demanded much courage and persuasion.

It was not, however, on the administrative side alone that Tizard made such an important contribution. Just as he had earlier insisted that aircraft engines should be tested on fuels more advanced than those generally available in peace, so now he saw that other factors, beyond the technical performance of the radar equipment, would have to be pursued if the whole system was to be made ready in minimum time. Above all, the Royal Air Force would have to develop tactics and a control system designed to get the best out of the radar data. He therefore proposed in 1936, before the radar defence chain was built, that it should be assumed to exist and to be capable of providing the appropriate plots on raiding aircraft. The system could be simulated by flying an intruding aircraft along the predetermined raiding course, and feeding its 'plots' to the defence system. Practical trials could then be made to evaluate whether the data were sufficient to promote successful interception, and whether one interception technique was more suitable than another. The trials were conducted in 1936 from Biggin Hill, and the serving officers and scientists concerned still retain warm memories of Tizard's personal impact while the interceptions were being carried out. He would talk to anyone, civilian or serving officer of whatever rank, if he could thereby gain contact with first-hand experience, or find a new suggestion for solving a problem. As a result of the trials, Britain not only had the radar equipment on which to base her air defence system in 1939; she also had the whole system manned by a body of men who knew how to use it.

### Infra-red

It was at this point that I met Tizard for the first time. Almost by accident, I had been drawn into the air defence problem, because of my work in infra-red spectroscopy and in particular on infra-red detectors. This was in February 1935, when an American inventor giving a demonstration of infra-red detection at Farnborough asked me to make him a replacement thermopile for his own, which had broken down. Lindemann, finding that one of his young research workers had been drawn into the air defence problem in this unofficial way, then pressed the Tizard Committee to support the work. The Committee had already considered infra-red and dismissed it as unlikely to be useful; but it later realized that there might just be some hope that it would provide a method of detection which might enable a night-fighter to close to within visual range of its target, since the nearer the approach, the bigger the infra-red signal from the heat of the

bomber's engine. I have recounted the details of the story elsewhere. In brief, we had an infra-red detector flying in an aircraft at Farnborough in 1937, and it might if necessary have been developed, albeit with difficulty, to the required performance; but, by that time, airborne radar looked distinctly more promising, and the Tizard Committee thought of closing the infra-red work. Before they did so, however, I was invited to appear before them, and so met Tizard for the first time. Tizard was not sure about closing the work, but was not happy about its proceeding at Oxford, still in Lindemann's laboratory, and he invited me to lunch a few days later at the Imperial College of Science and Technology to discuss the possibility of moving the work there. Lindemann, when I told him that I was going to lunch with Tizard, warned me of the dangers I was letting myself in for, even by accepting an invitation to lunch. I therefore went up to London in some apprehension, and was shown into Tizard's room. His first remark to me was: "I don't suppose that you can remember the First War". My reply was that I could remember the First World War very well. I told him that I had been through all the London air raids and, remembering my own experiences as a child in them, I was wanting to do whatever I could to stop them happening again. Not only that, while I could not remember in detail August 4, 1914, I could certainly remember November 11 of that year, when my father went to France, and there were incidents that I could remember in the spring of 1913 when I was not more than 18 months old. Tizard said: "That's very interesting. You have a longer memory than anyone I know—except myself. Do you know. I can distinctly remember having had a bottle!" This, coming from the ogre that Tizard had been painted to me, was a most unexpected start to a quite unexpected friendship. He went on to talk to me about "this silly quarrel" between Lindemann and himself, and we had a cordial discussion of what might be done with infra-red and, for that matter, with radar.

I did not see much of him for the next two years, because the infra-red work, which was of minor importance, was transferred to the Admiralty Research Laboratory, and I went there with it.

### Scientific Intelligence

My next contact with Tizard was closer, and arose through the realization, in the discussions of his Committee in 1938 and early 1939, that we really knew very little about what the Germans were doing in the fields of air defence and offence technology. Tizard persuaded the Intelligence authorities to accept a scientist for a trial period to see whether he could find why it was that we knew so little, and suggest ways of improvement. Again, to some extent by accident, the choice fell on me, very largely due to the suggestion of Mr. A. E. Woodward Nutt, then secretary of the Tizard Committee, that I might do the job. I had, between Oxford and the Admiralty, spent a few months in Air Ministry headquarters in 1938, and Woodward Nutt had found that I was very interested in Intelligence.

Tizard came into the Air Ministry in September 1939 as scientific adviser to the Chief of Air Staff, and I began to see him fairly frequently, since I had been attached to the Intelligence Directorate of the Air Staff. I can remember him telling me: "Get a big map and stick it on your wall. You will have nothing to put on it now, but sooner or later you will have plenty". I felt rather ostentatious when I followed his advice, but that map finished the war with 740 German radar stations pinned to it.

Lindemann was, of course, in the Admiralty with Mr. Churchill. Since I was attached to the Air Staff, and felt a moral responsibility to Tizard, I kept right out of Lindemann's way through the winter of 1939. I used, however, to have lunch with his assistant, James Tuck, from time to time, and one day in early 1940

Lindemann found a message on Tuck's desk saying that I would telephone again. He sat at Tuck's desk until I called, and immediately wanted to know why I had not been to see him. I explained that I personally felt some difficulty, but that if he particularly wanted to see me I would certainly respond. Immediately afterwards, I went to Tizard and explained that I had done my best to keep out of the controversy, but faced with this direct invitation from Lindemann, my old professor, I felt that I ought to go but that he, Tizard, ought to know that I was going. Almost to my surprise he said: "I am glad. I think that you ought to go, and as a matter of fact you could do some good. Please tell Lindemann from me that if he is prepared to bury the hatchet, at least for the duration of the War, I shall be very glad to do so. We have got enough on our hands fighting the Germans, without fighting one another". I went off, naturally delighted. I explained to Lindemann what Tizard had said, but was much rebuffed by his comment: "Now I am in a position of some power, a lot of my old friends have come sniffing around". So, most unfortunately, no headway was made.

Tizard found his position increasingly difficult, but he continued to advise the Air Staff on all aspects of air warfare, and to cover other border matters, including the possible applications of nuclear energy. Although he was far from convinced about the possibilities of a practicable nuclear weapon, he had a year before tried to stake a British claim on the uranium output of the Katanga mines. Now, in the winter of 1939-40, he instituted a sub-committee of the Committee for the Scientific Survey of Air Warfare (which had succeeded the original Committee for the Scientific Survey of Air Defence together with a parallel committee for air offence, formed in 1937 under Tizard's chairmanship), under Prof. G. P. Thomson, to look into the question of nuclear weapons. This was the famous 'Maud Committee'.

When Mr. Churchill became Prime Minister, Tizard's position became rather more uncertain because, while he advised the Chief of the Air Staff, Lindemann was now directly advising the Prime Minister. The detailed story of what then happened is being described by Mr. Clark—and so there is little need for me to comment. Tizard in effect vacated his post with the Air Staff; it was an ironic loss because this was the time when we realized, in June 1940, that the German Air Force presented us with a night threat the accuracy of which was enhanced by radio aids such as the beams, which had hitherto been neglected in Britain. The fact that we were able to spot them in time was the first success of the Scientific Intelligence effort and, as I recorded at the time, it had been "fostered by Sir Henry Tizard, Mr. Pye, Wing-Commander Winterbottom and Mr. Woodward Nutt (and opposed by the Treasury)".

### The Tizard Mission

At the end of June 1940 Tizard resigned from his post as Scientific Adviser to the Chief of Air Staff; but he was persuaded to retain his chairmanship of the Aeronautical Research Committee. Some time before, he had suggested that scientific co-operation with the United States should be advanced by attaching a scientific adviser to the British Ambassador in Washington, Lord Lothian, who had already suggested to the British Government that an interchange of scientific information and service experience should take place between the two countries. A. V. Hill therefore went out as an Attaché to Washington in May 1940 but, finding that he had an insufficient mandate to release information, he came back to London to press for stronger action. As a result, Tizard was asked to head a mission; Tizard wrote his own terms of reference, which were approved by the Prime Minister.

"To tell them what they want to know, to give all assistance I can on behalf of the British Government to

enable the armed forces of the U.S.A. to reach the highest level of technical efficiency."

Other members of the Mission included J. D. Cockroft and R. H. Fowler. They carried with them many technical secrets, including the 10 cm magnetron and the proximity fuse. They also carried, perhaps without specifically realizing it, the great secret of co-operation between science and the Services. The impact in September 1940 of the Tizard Mission on military and scientific thinking in the United States was immense. The revelation of so many secrets without guarantee of an adequate return was an act of balanced courage, in which Tizard's judgement must have been a predominant factor. Thereafter there remained, except perhaps in the field of nuclear energy an exemplary co-operation between the two countries on scientific matters throughout the War.

One permanent effect on American organization of defence science arose almost incidentally from the Tizard Mission, and resulted in a substantially different organization in the United States from that which has developed in Britain. In Britain we have grown accustomed to defence research (and much civil research) being done primarily in Government establishments. This system has obvious advantages, but also one serious drawback. It results in a dichotomy between much of our scientific research potential and the teaching duties that have to be undertaken in order to bring on the next generation. The history of the dichotomy is a long one, going back into the nineteenth century. In the United States, in 1940, defence science was more rudimentary than in Britain, and there were few strong government establishments. When the Americans realized, as a result of what Tizard showed them, how much they had to catch up, they appear to have decided that there was no time to set up new Government establishments, but that the best thing would be to build defence laboratories on to existing institutions like the Massachusetts Institute of Technology. The Radiation Laboratory there was a paramount example. It worked very well and, as a result, the pattern was perpetuated in post-war America. We in Britain used to have doubts about the wisdom of this course, since it seemed that the teaching and pure research at universities might be unduly influenced by the large amount of contracted research for defence. There are undoubtedly dangers in this, and they have not all been avoided; but, on balance, it is questionable whether we have done as well as the Americans by building up our Government establishments at the expense of the universities. Much could be said on both sides of this topic, on which Tizard's own views would have been particularly interesting now that there has been time to watch the developments. We can only note here that the quite substantial difference in pattern on the two sides of the Atlantic arose, and that the universities of America seem to have benefited a great deal.

### The Air Council

Tizard's advice continued to be sought and listened to by the Air Staff, much as Smuts's was by the War Cabinet. I have several recollections of his being called in when urgent problems arose, such as the wanton loss of one of our prototype 'Gee' receivers in an attack on Hanover in 1941, and the exploitation of the Bruneval raid in 1942. There was another occasion in 1941 when a scheme had been advanced to Sir Charles Portal for the co-ordination of all scientific work in the Air Ministry under one head; this would include in particular Operational Research and Scientific Intelligence, and there was little doubt, from the way in which the scheme had been proposed, whom the proposer intended to head it. Fortunately, Sir Charles Portal called in Tizard almost as an inspector general, to investigate the scheme and advise on its feasibility. The first thing Tizard did was to make a reconnaissance of all the relevant activities that were going to be absorbed

into this empire. He telephoned me, telling me what he had to do, and asking whether he could come and see the work of my office. At that time, the total staff of Scientific Intelligence was three, but we did not want to be absorbed into the new empire. We therefore decided that we must put on our very best show of efficiency and have our one room really tidy when Tizard arrived.

Again, as with our first meeting, things did not go at all the way that I had expected. The first thing that Tizard did when he walked in was to pick up a book that was lying on my desk, largely because there had been nowhere else to put it. It was the first volume of Gibbon's *Decline and Fall*, which I was reading in the train travelling to and from the office. Immediately Tizard said: "Hullo—who's reading this?" I replied that I was, and he said: "You know, there is some very good stuff in this". He went on: "I wonder whether this is the right volume. Let me have a look". A few moments later he said: "Yes, here it is. Listen to this!" He then proceeded to read part of what Gibbon had said about the younger of the two Gordians:

"Twenty-two acknowledged concubines, and a library of sixty-two thousand volumes, attested the variety of his inclinations, and from the productions which he left behind him, it appears that the former as well as the latter were designed for use rather than ostentation".

After this hilarious start, we settled down to a serious exposition of what we did, and I showed Tizard how we spotted radar stations on stereo-reconnaissance photographs. We had no really suitable place for an eminent visitor and so we sat him down at the desk of my colleague, Charles Frank, and let him look through the stereoscope. He continued to sit at this desk for the rest of the time. He was very interested, and we thought that we were doing rather well, and giving the impression that we were such an efficient unit that we required no co-ordinating direction from above.

Our impression of efficiency was shattered in a manner that we could never have foreseen. The door of our room was pushed open and a girl's head appeared. She was a very pretty and high-spirited cryptographer who had married one of my assistants, a flight lieutenant. She was in search of her husband, and thought that he might be in our room. She called out to me: "Hullo, Doc., have you seen Harold?" I replied as coldly as possible that I had not, and hoped that she would take the hint and disappear. Quite the reverse happened. She was, as luck would have it, very short-sighted but refused to wear glasses which would spoil her looks. She usually bluffed her way happily through the world without anyone knowing it. Not realizing our tense situation, she proceeded to come skipping into the room, and set about teasing Tizard, thinking with her blurred sight that he was Charles Frank. Ultimately she sensed that something was wrong, and to clear her view went right up and looked into the face of the man at the desk, while I and my colleagues wished that the floor would open and swallow up either her or ourselves. When her face was about two feet away from Tizard's she burst out: "Good God, it's Henry Tiz!" I can recall few more miserable moments. In that flash, it was quite obvious that we would have to be co-ordinated, and that such an irresponsible unit had no hope of survival. To my amazement, Tizard said: "Hullo, Maggie, what are you doing here?" By an almost impossible coincidence, it turned out that the girl and her family had lived some years before next door to the Tizards in Wimbledon, and Tizard was known to all the children as "Henry Tiz"—and he knew it. I can still remember my intense surprise and relief, for up to that moment I had thought that she had gone completely off her head. After that, of course, it was all plain sailing. On Tizard's recommendation, no empire was built and our independence was assured.

### President of Magdalen

After 1940, Tizard's appointment had been in the Ministry of Aircraft Production rather than in the Air Ministry itself, but he continued to see much of the Royal Air Force through his membership of the Air Council. Unfortunately, he did not have the scope that he merited, largely because of the great interest taken by Lindemann, quite naturally, in air matters. Since Lindemann was advising the Prime Minister directly, and since he had won the respect of the Air Staff through his actions on several important matters such as the establishing of the inaccuracy of our night bombing, Tizard's views could in effect be overruled. This was unfortunate, because there were important occasions when Tizard was right and Lindemann wrong. In the end, Tizard decided to get out and he accepted the Presidency of Magdalen in 1942. He resigned as chairman of the Aeronautical Research Committee in the following year. Even so, he was continually called back, notably to head an enquiry into the future of weapons in 1945.

### The Ministry of Defence

With the political changes of 1945, Lindemann himself returned to Oxford, and the new Government invited Tizard to re-enter the administration in London, as Chief Scientist at the new Ministry of Defence. I remember him telling me about this in his Lodging in Magdalen, and saying: "They don't know what they are asking me to give up". It was obviously going to be a very tiresome time in London, and would contrast sharply with the pleasant satisfaction of the headship of one of the most beautiful Colleges in Oxford. Nevertheless one could be quite sure that, having been called, Tizard would go. The next six years were full of frustration and exasperation, because the Ministry of Defence had no clear idea of what it was trying to do. The Service Ministries viewed it with much suspicion and, apart from presiding over the run-down both in British influence abroad and in our defence resources, the Ministry had to face the new situation created by nuclear warfare—in so far as that situation was clear through the veil of secrecy over atomic developments that screened some of these even from officers as high in the Ministry as Tizard himself.

### Science and the Services

Not long before he left Magdalen, Tizard lectured to the Royal United Services Institution on "Science and the Services" surveying his unique experience. Of the Tizard Committee he said: "The first time, I believe, that scientists were ever called in to study the needs of the Service, as distinct from their wants, was in 1935, and then only as a last resort. The Air Staff were convinced of the inadequacy of existing methods and equipment to defeat air attack on Great Britain, and a committee was established for the scientific survey of air defence. I want to emphasize that this committee, although it consisted on paper only of scientists, was in fact from the first a committee of scientists and serving officers, working together.

"When I went to Washington in 1940 I found that radar had been independently invented in America about the same time as it had been invented in England. We were, however, a very long way ahead in its practical applications to war. The reason for this was that scientists and serving officers had combined before the War to study its tactical uses. This is the great lesson of the last War."

Here he was saying again the things that he had said twenty years before in his inaugural address to this Society; but this time he could point to the great successes which had been achieved by putting into practice what he had previously advocated. The points that he made deserve all the emphasis that we can give them to-day, particularly because, while the urgency of war forces their wisdom on us, we are apt to drift from them in the

apparently less-pressing conditions of peace. He concluded:

"What is needed is a scientific staff attached to the central Chiefs of Staff organization that will have no executive duties, nor be overburdened by administration, but will devote its whole time to the study of the influence of advancing scientific knowledge on the problems of defence".

I do not know whether we have yet gone as far as he would have liked, but the present organization of science in defence is certainly better, I think, under the last reorganization than it has been at any previous time. There still remain some of the basic difficulties that Tizard himself had encountered after the First World War, in the way of attaining the wisest co-ordination of research effort, which nobody has yet mastered.

Perhaps we should not be too discouraged, because even a man of Tizard's flair and insight could not always succeed so well as he did in air defence. The parallel pre-war Committee on Air Offence, in particular, was nothing like so successful, despite his chairmanship. Of this Committee he himself noted: "It did not meet with such enthusiastic welcome from the Air Force. As a result, its influence before the War started was only small". The lesson here is that even Tizard could not succeed unless an Armed Service was prepared to face its own defects and call in help to deal with them. That our Armed Services are now much more prepared to do this than they were before the War is very largely due to Tizard's example and influence.

#### Higher Education and Research

The other difficulty that he had faced in the 1920's was that which I had already mentioned, of having to co-ordinate a number of independent organizations. I should much like to have discussed this problem with him during the past few years, because this is a problem that we face increasingly to-day. Starting at school education, for example, we argue that school and university education are part of the same process, and therefore that schools and universities should come under one Minister. Many of us also say that teaching and research go best together. Therefore research also should come under this Minister. Then we say that there has been too much separation between pure and applied research, and therefore this Minister should cover all pure and applied research. We also say that in the early stages of research, even applied research, it is difficult to say whether the end-product is going to be of more use in the military or in the civil field; in addition, we can point to the disadvantages ensuing from the separating of research from development, and development from the user. Therefore all military and civil research should stay together. In the end, we decide that everything from school education to military research, and from the most academic arts study to the most down-to-earth technology, are all part of one entity and are inseparable—and so, in some senses, they are. But it is obviously impossible to run them all under a single administrative department, and yet it is undesirable to have too rigid a division. The problem of finding the optimum compromise is extremely difficult, as can be evidenced by some of the better of Parliamentary debates in recent years. I have in mind, for example, the debates on the Robbins Report, and those discussing the relation between the Ministry of Aviation and the Ministry of Defence, and on the Trend Report.

#### President of the British Association

Whatever uncertainties we might have about how Tizard would now view our administrative problems, he made it pretty clear in his Presidential Address to the British Association for the Advancement of Science in 1948 what he would think of our present expansion in higher education:

"Whatever may be done, in a burst of public enthusiasm to support and promote schools of research at universities, nothing should be allowed to lower the quality; and size beyond a certain point, undeniably does. . . . When a young graduate tells me, as one did recently, that he was going to do research because it got him off military training, it makes me wonder whether we are not already over-populating the research departments of universities. . . . It is not the general expansion of research in Britain that is of first importance for the restoration of its industrial health, and certainly not the expansion of Government research remote from the everyday problems of industry. What is of first importance is to apply what is already known. The fact is that all really new developments of industry are the product of the work of very few men".

These views may conceivably sound rather old-fashioned now, but I personally believe that there is a great deal in them, and we miss the voice of Tizard in checking the near panic for higher education at all cost.

In passing, we may note that Tizard, for all his faith in science and technology, was not thrown off balance by the spectacular development of nuclear energy, for in his Presidential Address to the British Association he said:

"I shall certainly assert that the production of power from uranium cannot bring such economic benefits to Britain within twenty years as would the practical application of known methods of economizing coal".

This statement looked peculiarly old-fashioned to a scientific world overflowing with enthusiasm for the newest technology, but Tizard appears to have been right. The improvement in the efficiency of conventional power stations is one of the reasons why the nuclear power station has not been so widespread as then appeared likely.

#### Higher Education

As for what he said in 1948 about education, this was not the first time he had spoken on this subject to the British Association, for he had been president of the Education Section in 1934. His address then is well worth reading. It is, as usual, full of wisdom, and reads as topically to-day as it did thirty years ago. I can only quote two passages:

"No scientific man desires to see scientific education pushed to the neglect of literary studies; all of us recognise that a properly balanced diet for the mind is as important as for the body: what we do think is that science, well taught, can supply all that is best in the classical tradition; can 'teach accuracy and exactness; can give a discipline in clear thinking; can teach boys to recognise differences in things which seem alike; can brace with its difficulties minds that are not afraid of difficulties; can inspire with its beauty minds not insensitive to beauty'—to quote the recent words of the Headmaster of Rugby in praise of Greek".

And of who is fit for university education:

"Where shall we draw the line? There are many students who occasion no misgiving. They are those who are capable of teaching themselves, given the opportunity. To them, and ideally to all, the attitude of the university should be this: We give you here the opportunity of learning, if you wish to, from masters of their subjects; we give you access to well-equipped libraries and laboratories; and opportunities for learning from each other. We help you to help yourselves. What use you make of these opportunities depends upon yourselves. If we find you do not, or cannot, make good use of them, you shall go, and make room for others. Broadly speaking, I believe that is the right attitude. In such an atmosphere, learning, individuality and self-reliance flourish; and public expenditure is worth while. Judged from this standpoint, I have little hesitation in saying that universities are too full. As a result the tendency is towards over-organisa-

tion, too little latitude, and too much spoon-feeding. The more distinguished the teacher, the more he is tempted away from teaching and research: his presence is required on committees. In London we elderly gentlemen even organise students' athletics; and official debates take place on such important questions as the site and finance of a university boat club for women. The wider we fling open the doors to a university, the more will such organisation be necessary, and the worse will be the conditions for the best teachers and students".

When we remember that Tizard was speaking when the proportion of the population at universities was substantially less than it is now, that he was always on the side of the young and the progressive, that he wished to encourage the spread of education in science and technology, and that he was one of the most experienced and wisest educationists of our time, are we not forced to wonder whether the present expansion of higher education is well founded?

### The Messel Lecture, 1952

Tizard elaborated his point of view in the Messel Memorial Lecture which he gave in 1952 on "The Strategy of Science". Here he concluded with:

"It is more important now to strengthen our technology than to expand our science; more important to do things than to write about how they might be done. Science is not enough. We haven't any money, so we've got to think".

Incidentally, that lecture was given in Aberdeen, and was the principal event of the annual meeting there of the Society of the Chemical Industry. My wife and I gave a cocktail party for various members of the Society and its guests, including, of course, Tizard and also Niels Bohr, who happened to be staying with us. The party was immediately before the main Society dinner, and we were all in full evening dress with decorations. The party taxed our limited domestic arrangements, but these we had successfully negotiated or, as in the case of Tizard's visit to my office of ten years before, thought we had. Perhaps memories of what happened then led me to keep an involuntary eye on the door. Well, it happened again. This time, however, the young lady concerned was not a pretty cryptographer, but my small daughter, not then two years old. She had been banished and bribed to her bedroom for the duration of the party, but she had decided that she must help with the entertaining, and slipped in wearing her nightdress. It was not easy to follow her through a party of about forty people; in fact, for some time no one else noticed her, until she surfaced in front of the chairman of Imperial Chemical Industries, offering him a rather sticky handful of potato crisps. Tizard, who was obviously very fond of children, immediately took charge of the situation. The up-shot was that all the guests were shepherded to the periphery of the room while Tizard joined up with Niels Bohr linking hands behind their backs, and my small daughter drove these two eminent gentlemen around the room as a pair of horses, steering them with one hand grasping the Order of the Elephant and the other the Grand Cross of the Bath, the one on the left being commanded as 'Borie' and the one on the right as 'Tizzie', to the general applause of the spectators. Never, when I had first read Niels Bohr's name in my school books, did I think that I would be privileged to see such a human incident.

### Retirement

This happened at the stage when Tizard was relinquishing his work at the Ministry of Defence, but I saw him in London from time to time, since I myself had work to do there. One Monday evening, about three months after the cocktail party incident, he was in the chair at a discussion dinner at the Athenaeum, where Sir Stephen King-

Hall was leading a discussion on "Delusions in Defence". Sir Stephen was making points that were both provocative and wise, the main one being that we might well be in danger of losing the 'cold war' against Russia through undue concentration on a hot war, which he did not believe that the Russians intended to wage. The discussion went on for some time, but appeared to be in danger of drying up when Tizard in a characteristic manner got up and said: "Well, all this has been very interesting, but we have only heard so far from the older men, who would not be directly involved in fighting the next hot war, if it should come. What I should like to hear [and here is the true Tizard] is the views of some of the younger men—someone under forty". He looked around the dining tables and, spotting someone in this category, said: "You, Sir, over there. Please get up and tell us what you think".

By a fluke, I happened to know the young man he had picked on, because I had met him for the first time two days previously at a wedding in Cambridge, where he had been best man and I was giving the bride away. I saw him stand up, swallow hard, and start to speak. I thought, from my short earlier contact with him, that he would do pretty well, because, as a barrister, he was accustomed to speaking, and this had been borne out by his performance as best man. He made a slightly hesitating start, but got on very well, explaining that he had commanded a motor torpedo boat during the War, and going on to describe his reactions at having to serve again. Everyone was very pleased, and the discussion finished shortly afterwards. Later that week I had been invited by the young barrister and his wife to a cocktail party, and I greeted my hostess by telling her how well her husband had done, impromptu, at the Athenaeum dinner. She surprised me by saying: "It wasn't quite impromptu. He went along all prepared to speak". I was puzzled, because Tizard's challenge had been very naturally delivered, and the surprise on the barrister's face had been quite evident. His wife then went on to explain that he had attended as a guest of a psychiatrist member of the Athenaeum who had said to him some weeks previously: "You ought to come along one day to one of our discussion dinners at the Athenaeum. I have got a list of the topics here, so let's pick one that we know something about". The first one on the list was on "Delusions in Defence". The psychiatrist knew perfectly well what delusions were, and the barrister knew what defence was. They therefore deduced that the dinner was going to discuss the plea of insanity in murder trials, which was topical on account of the Straffen case, and the application of the M'Naghten rules. In preparation each had briefed himself thoroughly; it was only when the discussion started that they realized that the delusion was theirs. Tizard was delighted when I told him what had happened.

This story, showing Tizard in retirement but as ready as ever to encourage youth to expression, must close my account. I have rambled between national events and personal anecdotes in the hope of drawing a warmer and more faithful picture than a formal memoir could portray. Even so, I have by no means measured the breadth of his interests and achievements. His prescient administration of the Imperial College of Science and Technology, and his work in the Commonwealth, for example, deserve notice that I have had to omit.

Integrity, physical courage, moral courage, energy, humanity and humour were all ingredients in his character to a quite unusual degree. Among the newer fields of human experience, aeronautics gained especially from his enthusiasm and foresight, and it has therefore been a high privilege for me to make this personal salute before this Society. Intense patriotism combined with common sense and deep wisdom made him the architect of understanding between science and the Services exactly when this understanding was vital to our survival; and he championed the full part that science and technology could play in human life throughout the world. May we always

remember, by the practical examples that he set, the lessons that he so effectively taught.

## ROYAL SOCIETY VOLCANOLOGICAL EXPEDITION TO THE SOUTH ARABIAN FEDERATION AND THE RED SEA

By DR. I. G. GASS, DR. D. I. J. MALLICK\*

Department of Geology, University of Leeds

AND

DR. K. G. COX

Grant Institute of Geology, University of Edinburgh

UNDER the aegis of the Volcanological Expeditions Committee of the Royal Society, and financially supported by the Royal Society and the Universities of Leeds and Edinburgh, a three-man expedition spent three months in the South Arabian Federation and the Red Sea examining the recent volcanics of that region. The aims of the expedition were to study the coastal volcanoes between the southern entrance to the Red Sea and the Aden peninsula, the western part of the extensive coastal volcanic field to the east of Aden, and the volcanic islands of the Red Sea. These aims were achieved and, in addition, a brief visit was made to the recent volcanic cones near Ataq, 175 miles north-east of Aden.

Published geological data on the area are mainly petrographic, describing specimens collected by individuals and expeditions, little attempt having been made to map or to elucidate the volcanic history of the area concerned. Significant contributions to the volcanology of South Arabia and the Red Sea have been made by Vellain<sup>1</sup>, McMahon<sup>2</sup>, Raisin<sup>3</sup>, Prior<sup>4</sup>, Bier<sup>5</sup>, Manasse<sup>6</sup>, Vredenburg<sup>7</sup>,

Teilhard de Chardin *et al.*<sup>8</sup>, MacFadyen<sup>9</sup>, Wissman, Rathjens and Kossmatt<sup>10</sup> and Shukri and Basta<sup>11</sup>.

### Central Volcanoes on the South Arabian Coast between Aden and the Red Sea

Along the south coast of Arabia, between Aden and the southern entrance to the Red Sea, there are six geologically recent volcanoes. From east to west these are: Aden, Little Aden, Ras Imran, Jebel Um Birka, Jebel Khariz and the Perim-at Turbah mass. All are central vent volcanoes characterized by the intimate interstratification of basic and intermediate lavas with acidic tuffs, some of which have comenditic affinities. So far as can be determined, the later stages of activity have, in all cases produced large central calderas, which have since partially or wholly been infilled with horizontal ignimbrites and lavas. It seems most likely that the calderas were created by explosive activity although formation by collapse cannot be precluded. Palaeomagnetic data<sup>12</sup> and the morphology of the cones suggest that the volcanoes were active about 1 million years ago.

**Aden.** The Aden peninsula, an area of about 12 square miles, consists entirely of volcanic rocks, the oldest of which belong to a radially inclined series of basic and intermediate lavas interbedded with lensoid masses of rhyolitic composition and layers of coarse volcanic agglomerate which formed the original cone. Although most of this extrusive material was derived from a central vent, there are parasitic cones on the flanks from which basaltic lava and scoria were emitted. A subsequent phase removed the central part of the volcanic pile leaving a near-circular caldera some two miles in diameter. This cavity was filled by horizontal rhyolitic extrusives and trachyandesitic lavas. At a later stage, further, probably explosive, activity formed a second caldera slightly smaller than the first, and centred a little farther to the

Fig. 1. South Arabian Federation and the Red Sea

\* Present address: Department of Geology, University of Durham.

east. This, in turn, was partially filled by volcanic agglomerate and pumiceous tuff. Dykes are abundant and are radially disposed. Differential erosion has removed much of the radially-inclined sequence so that the horizontal rocks that filled the earlier caldera are now topographically eminent and form the horse-shoe range of hills known as Jebel Shamsan.

*Little Aden.* The peninsula of Little Aden has an area of about 16 square miles and, although the volcano is considerably more eroded than Aden, sufficient rock is exposed to make it quite evident that the two areas are structurally comparable. As in Aden, the oldest rocks are part of a composite cone of interstratified basic and intermediate lavas, rhyolitic effusives and agglomerates. Substantial remnants of this radially inclined sequence are preserved around the periphery of the area while the central and eastern part of the peninsula is partially occupied by horizontal basaltic lavas and rhyolitic ignimbrites that have filled in a large caldera. The dyke pattern is less obviously radial than that of Aden and has a marked east-north-east-west-south-west component. Erosion has removed much of the Little Aden volcanic pile, and large areas, particularly in the centre, consist of low plains covered with blown sand.

*Ras Imran.* Some 10 miles west of Little Aden there is a group of small hills forming the promontory of Ras Imran and the island of Jazirat Aziz. These are formed of basaltic pahoehoe lava overlying yellow volcanic agglomerate. As at Aden and Little Aden, there are both aphyric and markedly feldspar-phyric basalt lavas. Isolated lenticular masses of rhyolitic composition occur at Ras Imran and also on Aziz island, but they form less than 10 per cent of the total rock outcrop. All units have a northerly dip, and it is thought that they represent the northern flank of a central-vent volcano, the centre and southern flank of which have been removed by marine erosion.

*Jebel Um Birka,* 45 miles west of Aden, is the largest of a cluster of about 10 hills which rises to a height of 784 ft. Many of the hills, including Um Birka, are so covered by blown sand that the rock outcrops are scarce and confined to the leeward flanks. Rhyolitic ignimbrites and agglomerates are the most abundant rock types with black aphyric basalts occurring high in the sequence. All the extrusive units appear to have a radial dip away from a centre lying to the south-west so that from west to east the dip changes from northerly through north-easterly to due east. At Ras Ghawa, 3.5 miles to the south-east of Um Birka, there is a lone hill formed mainly of feldspar-phyric basalt lavas dipping in a south-easterly direction. All these hills are probably remnants of the northern and eastern parts of a central vent volcano of the Aden type.

*Jebel Khariz* lies 60 miles to the west of Aden and, with the exception of Aden itself, is the best preserved of the coastal central-vent volcanoes. It covers a roughly circular area of about 100 square miles, rises to a height of 2,766 ft. and is characterized, as are all the volcanoes of this group, by the close association of rhyolitic ignimbrite and basaltic lava. In this case, acid ignimbrites and agglomerates form more than 90 per cent of the radially inclined cone sequence while lavas of aphyric and feldspar-phyric basalt are found only on the south-east and northern flanks. The central caldera is exceptionally well preserved as a huge amphitheatre some 5 or 6 miles in diameter. Within this caldera, remnants of a later stage of volcanic activity which partially filled the caldera with horizontally bedded rhyolitic ignimbrites, basaltic lavas and agglomerates form a spectacular central tower.

The *Perim-at Turbah* mass lies on the south-western promontory of Arabia that forms the eastern margin of the entrance to the Red Sea. Most of this volcanic mass lies within the Yemen and was therefore not accessible. Examination of the area from the sea and from existing maps and photographs strongly suggested that this is another volcano of the Aden type with interstratified rhyolites and basaltic lava. The only part of this mass

that was examined was Perim Island, which is part of the western flank of the volcano and is separated from the rest by the eastern, narrower straits of Bab el Mandeb. On Perim, black aphyric and feldspar-phyric lavas are the only rock types present, and, although no rhyolites were identified, the lavas examined have petrographic affinities with those collected from the other volcanoes of this group.

All six of these central volcanoes lie close to a line which trends just north of east, near to this part of the coast of South Arabia. It seems probable that the zone of weakness delimited by the line of volcanoes forms the northern boundary of the crustal depression of the Gulf of Aden.

So far, the only chemical analyses available are of Aden and Little Aden specimens, although preliminary petrographic examination has been made on samples from all these volcanic centres. Chemical analyses of specimens from Aden given in Shukri and Basta<sup>11</sup>, and of specimens collected by Prof. W. Q. Kennedy and Dr. von Knorring from Little Aden<sup>12</sup>, show that the comendites are characteristically acidic rocks with silica ranging up to 72 per cent, relatively low alumina and high total alkali content. cursory examination in thin section reveals that the majority of the comendites consist of partly resorbed phenocrysts of sanidine and occasional smaller crystals of aegirine in a fine-grained mesostasis of perthitic feldspar, quartz, skeletal riebeckite and glass. The lavas range from olivine basalts through basalts to trachyandesites and trachytes. Olivine basalt and trachyandesite appear to be the dominant rock types and mineralogically the association has alkaline affinities. The two basalts that have been analysed are atypical, feldspar-phyric rocks highly charged with ore; this is reflected in the analyses which show high alumina, high combined iron ( $\text{Fe}_2\text{O}_3 + \text{FeO}$ ) and low  $\text{MgO}$ . In view of the wide range of rock types present in the volcanoes of this group, and in the unusual chemistry of individual types, the petrogenetic problems posed by this association are likely to be of considerable interest.

### The Shuqra Volcanic Field

In the Shuqra volcanic field, 70 miles north-east of Aden, very recent volcanics are widespread and consist of numerous cinder cones, many still perfectly preserved (see Fig. 2), associated with lava flows of black aphyric, feldspar-phyric and olivine-phyric basalts that have filled the irregularities in the pre-existing landscape. The pre-volcanic rocks consist of Upper Jurassic sediments resting on schists and gneisses of the crystalline basement. The area had been deformed into a spectacular, strongly faulted monocline parallel to the coast of the Gulf of Aden, before the basaltic lavas were poured out.

Isolated specimens from the Shuqra field that have been studied under the microscope consist of euhedral phenocrysts of olivine (c.  $\text{Fa}_{15}$ ), clinopyroxene and plagioclase (c.  $\text{An}_{65}$ ) in an intergranular groundmass of plagioclase laths (c.  $\text{An}_{60}$ ), granular clinopyroxene and granular iddingsite after olivine. Minute euhedral crystals of magnetite are scattered liberally throughout the rocks examined. These lavas appear to have mineralogical affinities with the alkali olivine basalt association.

*Ataq.* The town of Ataq, 175 miles north-east of Aden, lies in a sandy plain flanked to the west by granites and gneisses of the crystalline basement and to the east by an escarpment of Cretaceous and Lower Tertiary sediments. Three low hills formed by recent volcanic activity lie to the north of the town and are aligned in a north-westerly direction. These hills probably mark the northernmost extension of the Shuqra volcanic field. Two volcanic centres just to the north of Ataq were visited.

The southern volcanic mass is formed, for the main part, of black aphyric basalt which has flowed northwards from a vent near the southern margin of the mass. Two to three miles further to the north, there is a low eminence, some 200 ft. high, formed of volcanic material which is now partially covered by blown sand. This hill, locally

Fig. 2. Typical topography of the Shuqra volcanic field showing a well-preserved volcanic cone (centre) and an outlier of Upper Jurassic sediments (right)

known as 'Kirsh', consists of a well-preserved, circular crater some 200 yd. in diameter surrounded by a low rampart of volcanic agglomerate and basaltic lava spatter. To the north, a small lava field appears to have issued from the flanks of the cone. This centre is particularly notable for the agglomerate, which, in addition to the blocks of olivine basalt, contains abundant non-volcanic xenoliths. The non-volcanic xenoliths include schists and granitic gneisses, undoubtedly derived from the crystalline basement, and dunitic nodules which possibly originate in the upper mantle. The ultrabasic nodules are up to 9 in. in length in the agglomerates, but also occur in the lavas, where they rarely exceed 1 in. or are represented by solitary olivine xenocrysts. The dunites are completely fresh and show no sign of reaction at the margins; preliminary examination in thin section reveals that they consist mainly of forsteritic olivine, with chrome diopside, amphibole and spinel as minor constituents.

### The Red Sea Volcanic Islands

Volcanic islands are present only in the central southern part of the Red Sea and occur in three separate areas. These, from north to south, are Jebel Attair ( $15^{\circ} 33' N$ ), the Zubair group ( $15^{\circ} 12' - 15^{\circ} 00' N$ ) and the Zukur-Hanish group ( $14^{\circ} 05' - 13^{\circ} 31' N$ ). Many of the islands are single or double cones formed entirely of yellow basaltic agglomerate, while on the larger islands black basaltic lavas are abundant. Volcanic forms are well preserved (see Fig. 3) and all the islands are the products of geologically recent volcanic activity.

Jebel Attair, a solitary island measuring 2.5 by 1.5 miles, is centrally placed in the Red Sea trough and rises to a peak 800 ft. above sea-level. Radially inclined lavas of mainly aphyric and feldspar- and olivine-phyric basalts are the dominant rocks. Black and red cinder cones are numerous and lie on well-marked open fissures. These fissures are concentrated in three directions,  $310^{\circ}$ ,  $342^{\circ}$  and  $013^{\circ}$ , while the elongation of the Red Sea trough in this area is  $330^{\circ}$ . The vent at the summit gives off small quantities of steam and sulphurous gases and is partially encrusted with sulphur.

The Zubair group, between 24 and 29 miles south-south-east of Jebel Attair, consists of 10 islands with numerous offshore rocks and shoals. The smaller islands consist of single or double cones of yellow basaltic ash and agglomerate in various stages of erosion, while Saba, Centre Peak and Jebel Zubair, the largest islands, have

extensive lava fields as well as numerous pyroclastic cones. The lavas, like those of Jebel Attair, are mainly feldspar- and olivine-phyric basalts. The structure of the largest island, Jebel Zubair, is dominated by a median rift that trends at  $342^{\circ}$  and is marked by gaping fissures which cut across cinder and spatter cones and basaltic flows which have issued from them. From the morphology of the cone it is apparent that all the islands of the group are of geologically recent age, while on Zubair a distinct sulphurous smell can be detected near some of the vents suggesting that they were active in historically recent times.

South of the Zubair group the median trough of the Red Sea loses its identity and the Zukur-Hanish group of islands is surrounded by shallow water of less than 5 fathoms. As in the Zubair group, 75 miles to the north-north-west, the smaller islands of the Zukur-Hanish group consist of cones of yellow basaltic agglomerate in various stages of erosion, while the larger islands, Zukur and Great and Little Hanish, have numerous volcanic cones and extensive fields of black basaltic lava. Eruptive centres on these larger islands lie along fissures which have a north-easterly trend. This is oblique to the Red Sea median trough and does not appear to be related to the major structural lineaments of the adjacent African mainland<sup>14</sup>.

Fig. 3. Haycock Island in the Zukur-Hanish group; a near-perfect volcanic cone of yellow basaltic ash and agglomerate some half-mile in diameter with a small cone of basaltic spatter within the main crater

So far only isolated specimens from the Red Sea volcanic islands have received preliminary examination under the microscope. All the specimens examined were olivine basalts, but there is considerable textural variation from strongly porphyritic to aphyric types but with a relatively uniform mineral content. The main rock-forming minerals are olivine (c.  $\text{Fa}_{12-20}$ ), clinopyroxene and plagioclase (c.  $\text{An}_{50-65}$ ). When present as phenocrysts, the olivine is euhedral and commonly zoned from a forsteritic core to a more fayalitic margin, while plagioclase phenocrysts, although within the labradorite range, are often progressively zoned from a calcic core to a more sodic rim. The ground mass is intergranular with minute, sub-hedral crystals of olivine and clinopyroxene occurring between laths of plagioclase. Volcanic glass, or its alteration products, is rare. Sufficient work has not been undertaken to establish whether there is any significant petrological variation between the rocks of the three island groups, but specimens examined indicate affinities with the alkaline rather than the tholeiitic association.

Petrographic investigation of the specimens collected in all areas is in progress at present.

We thank the chairman and members of the Volcanological Expeditions Committee of the Royal Society for their support and encouragement and the Royal Society and the Universities of Leeds and Edinburgh for financial assistance. We also thank the various branches of H.M. Forces for their assistance and hospitality during our stay in South Arabia, and members of the British Petroleum Company, Aden and Little Aden, and the South Arabian Federal Government for their generous assistance.

## OBITUARIES

### Prof. Hans Halban

PROF. HANS HALBAN, who died on November 28, 1964, at the age of fifty-six, will be widely remembered among scientists for his major contributions in slow neutron physics before the Second World War which led up to the successful realization of the nuclear reactor.

Halban was born in Leipzig on January 26, 1908, and after education in Austria he went to the University of Zurich, where he gained his Ph.D. in 1935, working in the laboratory where his father was professor of physical chemistry. He then moved to Mme Curie's Institut de Radium in Paris, and it was at this time that he started his research on slow neutron physics. In 1937 he went with a special scholarship to Niels Bohr's laboratory in Copenhagen and carried out neutron experiments with Frisch and Koch, which included a measurement of the neutron magnetic moment and a study of the internal field in a ferromagnetic substance using neutrons. He returned to Paris in 1938 to become Chargé de Recherches in the Laboratoire de Chimie Nucleaire in the Collège de France of which F. Joliot-Curie was director and where he continued his neutron studies. This culminated in his great work in 1939 along with Kowarski and Joliot-Curie on the neutrons from the fission of uranium. It was these experiments involving the moderation of neutrons in uranium solutions that first demonstrated the possibility of a chain reaction and, in a classic sequence of papers in that year, Halban, Kowarski and Joliot-Curie discussed the process together with methods for its control. This work was interrupted by the War and the fall of France in 1940, but Halban succeeded in escaping to England, bringing with him under dramatic circumstances the precious churns of heavy water. These 180 litres formed the greater part of the world's stock and had been purchased to extend the moderation studies in Paris. Under the auspices of the MAUD Committee this research was continued in the Cavendish Laboratory where Halban was in charge of the slow neutron team. As the effort on the project developed, so the active centre of research moved to Montreal and in 1942 he took charge of the joint British-Canadian team which included several distinguished French scientists and was concerned, among other matters, with the development of reactors. It was this work which finally led to the construction of the heavy-water reactor at the Chalk River Laboratories.

He resigned this appointment in 1945 and a year later went to Oxford at the invitation of Lord Cherwell, who

was then head of the Clarendon Laboratory. He quickly built up a team of research students which was set to work on problems both in neutron and nuclear structure physics. Many of these research students came from overseas and had been drawn to him through his wide contacts abroad and his international reputation as a physicist. Under his lively and imaginative influence the group flourished and produced many original papers on a wide range of subjects. The research was often hampered by shortage of funds and equipment, and with characteristic generosity he would contribute from his own resources to enable the work to continue. It was in 1951 that a co-operative effort between some of his nuclear physics group and a number of low-temperature physicists under the general direction of the late Sir Francis Simon showed that it was possible to attain a substantial degree of alignment of the nuclei of radioactive cobalt-60. This field of research, in which he had first become interested in 1937, soon developed into a powerful tool for studying problems in both nuclear and solid-state physics and is being actively pursued to this day in many laboratories. In 1950 he was made a fellow of St. Antony's College in whose foundation he was deeply interested, and in 1954 the University of Oxford conferred the title of professor on him. He returned to Paris in 1956 to become professeur associé at the Ecole Normale Supérieure and a director of the Orsay laboratory, where a high-energy electron accelerator was to be installed. He retired from active nuclear physics in 1963.

Halban will be remembered by his friends and colleagues, and not least by his research students, for his boundless enthusiasm, his originality and his continuous stream of ideas. He was critical of his own work and he demanded a high standard from others, but he tempered this with great understanding, generosity, warmth and loyalty. He was a dynamic character and a great physicist.

M. A. GRACE

### Prof. A. Voisin

AN internationally recognized figure, Prof. André Voisin died in Cuba on December 22, 1964, at the age of sixty-one, while engaged on a lecturing programme connected with the reorganization of the agriculture of that country.

The study of grassland and the grazing animal, by virtue of its complexity, has given rise over the years to many prophets: men of zeal, evangelistic by nature, and

all in some degree dogmatic. Undoubtedly one of these was Voisin. He came of Norman farming stock and trained as a biochemist in Paris and at Heidelberg. It was as a practical dairy farmer in his native Normandy, however, producing milk from grass, that he gained the experience synthesized in his philosophy of 'rational' or 'timed' grazing.

Voisin burst upon the British farming scene in 1957 with the publication of possibly his best book, *Grass Productivity*. Its translation into English was followed by translation into Russian, German, Japanese and Hungarian. Here he propounded his philosophy of grassland management, the 'rational' system, basically a rotational grazing system strictly governed by defoliation frequency in relation to rate of herbage growth. The success of this work stimulated further publications—*Better Grassland Sward*, and *Soil, Grass and Cancer*, and finally, *Grass Tetany*.

Throughout his writings Voisin stressed that the grass crop must not be considered in isolation. The sward, which in turn depends on the soil, should always be related to the needs of the grazing animal, its health, well-being and production. Sward management can favour the grazing animal or the sward at any point in the grazing season without much difficulty. The results, however, may not be ultimately satisfactory. Voisin's great contribution was the evolution of a simple grazing system, soundly based, which sought and obtained the best, at one and the same time, from both sward and animal within the limits of the potential available. His reasoning quickly found favour with progressive dairy farmers, who applied his ideas with advantage. Present-day research work in plant breeding and herbage variety testing, through the use of new techniques, particularly *in vitro* studies of digestibility, is directed at taking into account the elusive 'quality' factor in fodder: in other words, the ultimate value of the feed to the animal in terms of net output. Voisin realized at an early stage that production of dry matter *per se* was not the whole answer. All his writing emphasized consideration of the needs of the animal in order to obtain optimum results.

It was unfortunate that most of his thinking centred on the permanent pasture as the most suitable medium for the dairy cow. His philosophy, moreover, hinged on only moderate use of fertilizers. Under conditions in

Britain, however, the permanent sward, because of its normally small legume contribution, is dependent on heavy fertilizer input for high herbage production, and for this reason Voisin, perhaps unknowingly, never quite completely reconciled his approach from his continental background with the fundamental economic needs of the dairy farm in Britain. These have been clear-cut over the years and have given rise to marked intensification of production determined largely by high fertilizer nitrogen application and a growing dependence on the short-term ley as a means of lengthening the growing season. In this context, Voisin's views on the 'sacrifice' of animal and plant in the cause of blind intensification of production were timely.

His brisk, forceful style and completely convincing manner, both as writer and lecturer, gained him wide popularity while provoking much controversy, to the benefit of farmer and scientific worker alike, for he gave even the most experienced grassland and animal workers cause to stop and think. From his wide knowledge of the literature, Voisin made more than a reasoned case for most of his conclusions, including those on human health arrived at in his highly controversial work, *Soil, Grass and Cancer*. His omnibus approach obviously caused him to conflict with many specialized views, but one of his great attributes was that, although acutely aware of the trees, his great concern was with the wood: the conclusions he reached were most difficult to dismiss lightly.

Above all, Voisin was a master in public relations. He aimed directly for his audience, the farming community and being a farmer himself, he knew exactly how to orientate his arguments to gain the most telling effect. His boundless energy and enthusiasm, not forgetting his humanity, are reflected throughout his work. Voisin's contribution to grassland farming practice was very large: Normandy may well be proud of her son, who found world favour in his chosen field.

Among the many honours he received abroad was an honorary degree from the University of Bonn. He was a member of the Académie d'Agriculture of his own country and also held the Croix de Guerre gained during the Second World War.

CATHERINE HERRIOTT

## NEWS and VIEWS

### Chemical Crystallography in the Imperial College of Science and Technology : Prof. D. Rogers

DR. D. ROGERS, reader in chemical crystallography in the Imperial College of Science and Technology, has been appointed to the newly established chair of chemical crystallography in the Department of Chemistry of Imperial College. Although 'born and bred' a physicist, he enjoys a national and international reputation as an X-ray crystallographer, combined with a lively interest in computers and programming. Dr. Rogers was educated at Wallington (Surrey) Grammar School and graduated in 1941 at King's College, London. After securing a Ph.D. in physics at King's College in 1944, he became assistant lecturer in the College of Technology, Manchester, where his early work on X-ray crystallography was carried out. In 1948 he moved to University College, Cardiff, where he remained as a close collaborator of Prof. A. J. C. Wilson until he joined Imperial College in 1961: he held an Imperial Chemical Industries fellowship for part of this period. Since his appointment as reader at Imperial College, he has established a thriving school of chemical crystallography. Dr. Rogers's prolific studies of crystal structures have been mainly among complex organic compounds, and substances of special biological significance have provided the main field for his recent work. Nevertheless, he maintains a keen interest in other struc-

tures, and has contributed much to the work of colleagues in inorganic chemistry, particularly in the study of metal complexes. He and his research school are substantial users of the *Atlas* computer in the University of London.

### Analytical Chemistry in the Imperial College of Science and Technology : Prof. T. S. West

DR. T. S. WEST, reader in analytical chemistry at the Imperial College of Science and Technology, has been appointed as from October 1 to the newly established chair of analytical chemistry, the first in this discipline in the University of London. Dr. West was born in Peterhead, Aberdeenshire, in 1927, and after education at Tarbat Old Public School and Tain Royal Academy, winning first place in the Scottish Education Department's 'Highlands and Islands' Bursary Competition, proceeded to the University of Aberdeen, where he graduated with first-class honours in 1949. He then gained his doctorate, under Prof. Belcher, at the University of Birmingham, obtaining also his D.Sc. there in 1962. He was lecturer in the University of Birmingham until his transfer to the Imperial College of Science and Technology in 1963. Dr. West was awarded the Meldola Medal of the Royal Institute of Chemistry in 1956, the first analytical chemist to have won this distinction. In addition to his productive research activities which have

resulted in many papers, Dr. West has been an active member of various committees of the Society of Analytical Chemistry, the International Union of Pure and Applied Chemistry, etc., and is a founder member of the editorial board of *Talanta*. Dr. West's researches have been concerned with the development of submicro methods of organic analysis, titrimetric reagents and the application of co-ordinating and chelating agents in inorganic analysis; he has also written several monographs and has been a contributor to the *Annual Reports of the Chemical Society*. In addition to his research interests, Dr. West is deeply concerned with teaching and is running a postgraduate course in analytical chemistry at the Imperial College of Science and Technology as well as supervising numerous research students.

#### Experimental Education in the University of Manchester: Prof. F. W. Warburton

DR. F. W. WARBURTON, senior lecturer in education in the University of Manchester, has been appointed to the newly-established chair of experimental education at that University. Dr. Warburton entered the University of Reading in 1928 and graduated with honours in psychology in 1931. In the following year he was awarded the Diploma in Education of the University of Reading and then took up an appointment as assistant master in the London Teaching Service. He held this post until 1940 and during this time he read for, and gained, an M.A. of the University of London. In 1940 he was appointed acting headmaster of the London County Council School, Solva, Pembrokeshire, Wales. In 1945 he took up an appointment as Fellow at the London Child Guidance Clinic and in the same year was awarded a Ph.D. (London). In the following year he was appointed research officer (with the rank of major) in the Department of Personnel Selection of the War Office. In 1948 he was made officer in charge of the research team in Far Eastern Command, Singapore and Ipoh, Malaya. In 1949 he was appointed lecturer in educational psychology in the Department of Education in the University of Manchester. During 1958-59 and also the summer of 1961 he was research associate professor in the Department of Psychology in the University of Illinois. He was promoted senior lecturer in the University of Manchester in 1960 and was visiting professor in the Department of Education in the University of Illinois during the summer of 1963. Dr. Warburton has been a Fellow of the British Psychological Society since 1948 and a member of the Council of that Society since 1960. In 1960 he was appointed a member of the Committee on the New British Intelligence Test. In 1962 he became secretary of the Society of Multivariate Experimental Psychology (European Branch) and in 1963 convener of the British Psychological Society Committee on Programming of Electronic Computers.

#### Electrical Engineering in the Queen's University of Belfast: Prof. E. H. Frost Smith

DR. E. H. FROST SMITH has been appointed to the chair of heavy electrical engineering in the Queen's University, Belfast, rendered vacant by the resignation of Prof. J. C. West on his appointment to the University of Sussex (*Nature*, 203, 815; 1964). Born in 1923, Dr. Frost Smith received his early education at the Whitgift School, Croydon, and, after the outbreak of the Second World War, at Ardyn, Aberystwyth. Going up to Peterhouse College, Cambridge, in 1941, he graduated B.A. in the Mechanical Sciences Tripos in 1943. From Cambridge, Dr. Frost Smith joined the research staff of the Royal Aircraft Establishment, Farnborough, where he worked on automatic control systems associated with the electrical equipment of aircraft. In 1947 he took up postgraduate work at University College, London, and in 1950 was awarded the degree of Ph.D. for research into the behaviour of magnetic amplifiers. Returning to industry the same year, in the research laboratories of

Elliott Brothers, Dr. Frost Smith continued his work on automatic control systems and, in 1954, he became chief engineer of the Servo Mechanisms Division of that Company. In 1956 Staveley Industries appointed Dr. Frost Smith director of research at Bedford. Here he has been responsible for a wide range of research projects, mechanical, hydraulic and electromechanical, related largely to the design and manufacture of machine tools and control systems. Dr. Frost Smith brings to his new post a keen interest in the problems of engineering teaching in universities and an exceptionally wide experience of industrial research. One of his specialist interests which he may be expected to pursue in his new department is the problem of developing the low-inertia high-torque electric motor for use on control systems.

#### Sociology in the University of Kent at Canterbury: Prof. A. P. Stirling

DR. A. P. STIRLING, who has recently been appointed to the chair of sociology in the University of Kent at Canterbury, is forty-four years old. After a period at the University of Oxford, interrupted by service in the Royal Navy as Lieutenant, R.N.V.R., during 1941-45, he gained a first-class honours degree in Litt.Hum. in 1947. From 1948 until 1951 he was the holder of a senior treasury studentship for Turkish cultural studies under the Scarborough Scheme. After training in social anthropology at Oxford he carried out comparative field research on two Turkish villages. For this work he obtained his D.Phil. degree in 1951. In 1952 Dr. Stirling joined the London School of Economics and Political Science as an assistant lecturer in anthropology, becoming a lecturer in 1954. During his period at the School he made very significant contributions as a teacher, as a research worker, and as an organizer of research plans. He also served with distinction as the managing editor of the *London School of Economics Monographs on Social Anthropology*. Dr. Stirling has published a number of articles on aspects of Turkish rural society and also a book entitled *Turkish Village*, which is a substantial, meticulously documented description of two Turkish rural communities in their general social, economic and political setting.

#### Scientific Director of the High Latitude Space Environment Monitoring Station, Anchorage, Alaska:

Dr. H. J. A. Chivers

DR. H. J. A. CHIVERS has been appointed the first scientific director of the Central Radio Propagation Laboratory's High Latitude Space Environment Monitoring Station, Anchorage, Alaska. In his new position, Dr. Chivers will direct the scientific activities of the Station as it reorganizes its activities in the field of space environment monitoring and forecasting. This change is being made to allow the Anchorage facility to concentrate on monitoring and reporting solar and geophysical events of importance to users of high-frequency radio propagation and to other activities affected by solar-associated disturbances in the space environment of the Earth. Dr. Chivers, who is a graduate of the University of Manchester, has been a senior scientist with the Space Environment Task Group, and has also served as chief of the High Latitude Ionospheric Physics Section, Upper Atmosphere and Space Physics Division, for two years. His research experience includes observation of radio star scintillations at the Jodrell Bank Experimental Station, University of Manchester, and radio observation of artificial satellites by means of ground-based stations for ionospheric research, geomagnetic conjugate point studies, and D region absorption at the National Bureau of Standards Boulder Laboratories. Dr. Chivers is a member of the United States Commission III of the International Scientific Radio Union, the American Geophysical Union, and the Polar Cap Panel of the Committee on Space Research.

### Admissions to Universities and Colleges of Advanced Technology

IN written answers in the House of Commons on February 18, the Secretary of State for Education and Science, Mr. A. Crosland, stated that about 19,275 students in science and technology were admitted to universities and colleges of advanced technology in October 1964, or 1,375 more than in October 1963, but about 2,000 fewer than had been planned. Recurrent Government grants to universities and colleges during the financial years 1961-62 to 1964-65 were: 1961-62, £57.9 million; 1962-63, £56.8 million; 1963-64, £69.4 million; and 1964-65, £86 million. The corresponding capital grants were: £26.2 million, £32.8 million; £40.7 million, and £57.5 million, respectively.

### Underground Transmission Lines

IN reply to questions in the House of Commons on February 16 regarding underground transmission lines, the Parliamentary Secretary to the Ministry of Power, Mr. J. Morris, said that out of a total expenditure on research and development of about £7 million a year by the Central Electricity Generating Board and the Area Boards, roughly £1 million was spent on transmission and distribution, of which between 10 and 20 per cent was spent on placing cables underground. Much research was carried out by manufacturers and supported by the Boards through their purchases of cables. The Central Electricity Generating Board had placed, or was placing, contracts of about £21 million for 275-kV and 400-kV cables of a pioneering type, with an exceptionally large cross-section and provision of water-cooling. These contracts reflected much indirect support for the cable manufacturers' research and development. The Central Electricity Generating Board was giving much thought to the possibility of underground cables, but for a 400-kV line the cost was about £1 million a mile—between 18 and 20 times that of taking it above ground. At March 31, 1964, 7.6 per cent of circuit miles of the Central Generating Board were laid underground and 40.9 per cent of those of the Area Boards of more than 650 V. In 1962-63 the Central Electricity Board incurred 47.5 per cent of its capital expenditure on transmission cable or underground cables, and 42.6 per cent in 1963-64; for the Area Boards the corresponding figures are 82.2 per cent and 83.6 per cent.

### Water Barrages

IN reply to questions in the House of Commons on February 16 about the supply of power from water barrages, the Parliamentary Secretary to the Ministry of Power, Mr. J. Morris, said that while the Central Electricity Generating Board had noted the work being done by Mr. E. M. Wilson in the Department of Civil Engineering at the University of Sheffield on a barrage for the Solway Firth and the plan for a barrage across Morecambe Bay, it had estimated that in the most promising schemes so far proposed in Britain, the cost of generating electricity by tidal barrage would not be competitive. In reply to further questions on February 18, the Parliamentary Under-Secretary of State for Economic Affairs, Mr. W. Rodgers, said that proposals for barrage schemes in the Solway Firth, Morecambe Bay and the Dee Estuary were already being examined in the context of regional economic planning and it was hoped to make a statement shortly. It was recognized that this was not just a matter of the generation of electricity but that roads, the conservation of water and many other factors had to be taken into account. It was most important to consider all these schemes together and not the merit of any one of them in isolation.

### Carnegie Institution of Washington

THE *Report of the President* of the Carnegie Institution of Washington for 1963-64 gives new information concern-

ing the most distant visible objects in the Universe; new estimates of the age of the Earth and the size of the Earth's core; progress in the understanding of how organs of the body are formed and how living cells differentiate (Pp. 73 + xi + 5 plates. Reprinted from *Carnegie Institution of Washington Year Book 63* for the year 1963-64, Washington, D.C.: Carnegie Institution of Washington, 1964). The age of the Earth is now given as 4.7 billion years, and the examination of samples of material from St. Paul's Rocks, a group of islands located on the mid-Atlantic ridge, gave an age of 4.5 billion years; this would make them the oldest known rocks on the surface of the Earth.

### Association for Education in France

*French Science News* (No. 2; April-June 1964) record the foundation of the Association for Education in France, to promote co-operation between university and industry within the scope of the science faculties of the Universities of Paris, Grenoble and Nancy. The board of directors consists of an equal number of university professors and industrial representatives. Premises are under construction at the Orsay Faculty. The first objective will be to train engineers to a high degree of scientific culture; for the two years following their qualification they will be given special tuition which will include the new branches of science best adapted to their future industrial career. The second aim is to organize full-time refresher courses, lasting from a week to a fortnight, for practising engineers; these courses are to provide either a general or specialized training.

### L'Association des Physiologistes

L'Association des Physiologistes held the first of its biannual meetings of 1965 at Marseilles during February 10-13. About 200 members attended; the four-day meeting was divided into two days of demonstration followed by two days of short papers and discussions. More formal lectures will be included in the programme for the principal meeting of the Association, to be held at the end of June at Louvain, Belgium. The Association was founded in 1926 and owed its inception particularly to Profs. André Mayer and Emile Terroine of Strasbourg. The early membership was drawn from France, Belgium and Switzerland. The words 'de la langue Française' were added to the Association's title soon after its formation, but with the extension of its membership in recent years to countries where French is not the native tongue the original title has been resumed. The proceedings of each meeting are recorded in the *Journal de Physiologie* published biannually in Paris.

### Nuclear Structural Engineering

AN apparently widespread feeling of dissatisfaction among engineers that existing nuclear engineering literature does not yet provide an appropriate outlet for material in the field of nuclear structural engineering has led to the establishment of the new international journal *Nuclear Structural Engineering*. It is devoted to the civil mechanical and chemical structural engineering problems of nuclear power plants, of radiation facilities and of radioactive waste. Particular aspects include heat transfer, stress analysis, the design, fabrication and testing of reactor components and materials, reactor layout and safety considerations, and radiation protection. The editor, Dr. T. A. Jaeger, is a lecturer in nuclear structural engineering at the Technical University, Berlin, and he is assisted by 26 section editors from sixteen countries including Japan and the U.S.S.R., but not China. The journal is to appear bi-monthly. The first number (January 1965) contains 12 articles, two notes and two book reviews, together with bibliographical notes concerning the section editors, and consists of 139 pages. Each volume, costing £9, will have about 500 pages. It is published in Amsterdam by the North-Holland

ublishing Company. Contributions may be written in English, French or German, but the abstract must always be in English. The text and diagrams are clear and well printed and the standard of the articles conforms to that of the better scientific journals. However, one article from the Franklin Institute is an abbreviated version of a chapter of a book shortly to be published, and the units used in several of the articles reflect whether the authors are engineers or scientists.

#### Bibliography of Dictionaries

A COMPREHENSIVE bibliography, processed by punched-card, machine-sorting, and photo-offset techniques, in which are listed more than 2,800 bilingual and polyglot dictionaries, glossaries and encyclopaedias published during 1952-63, has been compiled by T. W. Marton of the National Bureau of Standards, U.S. Department of Commerce (Miscellaneous Publication No. 58. Washington, D.C.: Government Printing Office, 1964. 1.25 dollars). The entries are subdivided into 49 subject classes covering the physical sciences, engineering and technology, and are listed in alphabetical order by language. Within each language group the entries are arranged alphabetically by author or title, and consist of the names of the individual or corporate authors, the original title of the work, an abbreviated translation of foreign titles, the imprint, the Library of Congress card number, and the approximate number of terms contained in the work. Forty-seven foreign languages are represented in the bibliography. Detailed indexes, by author, language and subject, complete the publication, which by its large coverage will be of great value to scientists and engineers, abstractors, technical information officers, librarians and translators.

#### Directory of Information Resources

A DIRECTORY has been published by the National Referral Center for Science and Technology at the U.S. Library of Congress. The book, of 356 pages, is entitled *Directory of Information Resources in the United States: Physical Sciences, Biological Sciences, Engineering* (available from Superintendent of Documents, Government Printing Office, Washington, D.C. 20402, 2.25 dollars). The volume contains narrative descriptions of the subject specialization, information services, and publications of some 1,100 organizations and institutions throughout the United States. Professional societies, academic research groups, industrial firms, Government offices and technical libraries are included. The National Referral Center, supported by funds from the National Science Foundation, is now preparing a similar volume in the social sciences, based on data gathered in a special survey by the Bureau of Applied Social Research at Columbia University. Plans are being made for specialized listings to meet specific requirements in selected areas.

#### Dual Effect of Boron and Manganese on Growth of Raspberries

DR. C. L. WHITTLES, Campbell House, Mauchline, Ayrshire, Scotland, has written to the Editor emphasizing the necessity of estimating the effects of micro-elements on plant growth more comprehensively than is frequently done. In a long-term experiment with raspberries (Burnet Holme Seedling) on ground well supplied with nitrogen, phosphorus and potassium, he failed to obtain any enhancement of vigour from applications of boron alone, even though leaves from treated plants had ten times the boron content of controls. Treatment with manganese borate (1 lb. per 20-yd. row, giving 20 p.p.m. boron and 15 p.p.m. manganese in the soil), however, gave spectacular increase of growth and fruitfulness. The variety Burnet Holme is apt to decline in vigour, even with adequate soil fertility, showing increasing amounts of 'die-back' and virus-like symptoms in the process. Dual application of boron and manganese arrested the decline and rapidly

restored the vigour, eliminating also the die-back and the virus-like symptoms. Apical buds of untreated plants, moreover, became dormant in August (a condition recognized by tea planters and called 'banjhi'). Application of manganese borate broke this dormancy, and within 72 h after treatment the shoot had begun to extend. It is possible, indeed likely, that response to manganese borate will vary on different soils, but the necessity for integrated investigation of micro-nutrients of plants is an important consideration arising from this work.

#### The Institute of Physics and the Physical Society: Appointments and Awards for 1965

THE Council of the Institute and Society has made the following appointments and awards for 1965; the presentations will be made in London at the annual dinner of the Institute and Society on May 4: *Guthrie Lecturer*, Dr. J. B. Adams, director of the Culham Laboratory of the U.K. Atomic Energy Authority; *Thomas Young Medal and Prize*, to Prof. A. Maréchal of the University of Paris and the Institut d'Optique, Paris, for his distinguished work in many fields of optics; *Duddell Medal and Prize*, to Dr. H. A. Gebbie of the National Physical Laboratory, for his pioneering work in interference spectroscopy in the infra-red; *Charles Chree Medal and Prize*, to Prof. B. J. Mason of the Imperial College of Science and Technology, for his work in atmospheric physics; *Charles Vernon Boys Prize*, to Dr. A. Howie and Dr. M. J. Whelan of the University of Cambridge, for their studies of lattice defects in crystals by electron microscopy.

#### Travelling Research Fellowships to Denmark and Sweden, 1965-1966

APPLICATIONS are invited for the Carlsberg-Wellcome and Wellcome-Swedish travelling research fellowships, 1965-66. The object of these is to encourage working visits, on an exchange basis, between Danish and British, and Swedish and British, investigators in any branches of the natural sciences which have a bearing on human and animal medicine. One of each fellowship is awarded annually to a graduate from the United Kingdom for a year's work in the exchange country, and one Swedish and one Danish candidate annually may work in the United Kingdom. The stipend may range from £1,000 to £2,000 per annum; travelling and some incidental expenses are provided in addition. The Carlsberg-Wellcome fellowships are arranged with the Carlsberg Foundation in Copenhagen; the Wellcome-Swedish fellowships are provided jointly by the Medical Research Council of Sweden and the Wellcome Trust. Candidates in the United Kingdom can obtain further information from the Scientific Secretary, the Wellcome Trust, 52 Queen Anne Street, London, W.1. Completed applications must be submitted by April 9, 1965.

#### Physics Exhibition

THE Physics Exhibition, 1965, will be held in the Manchester College of Science and Technology during April 5-8. The Exhibition endeavours to show recent advances in physics and its applications and in methods of teaching physics. Emphasis is placed on new scientific instruments and apparatus and their possible uses for improving productivity. During the Exhibition, the following lectures will be given: physical instruments in biophysical and biological research (Dr. A. Elliott, King's College, London); instrumentation problems in computer control systems (J. L. W. Churchill, A.E.I. Automation, Ltd.); instrumentation in process and product control in the textile industry (Dr. D. W. Hill, Cotton, Silk and Man-made Fibres Research Association). Further information and tickets can be obtained from the Secretary, Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

### John Logie Baird Travelling Scholarship

THE Television Society invites applications for the third award of the John Logie Baird Travelling Scholarship. This Scholarship, of value up to £200, is open to post-graduate students (in United Kingdom educational establishments) who are concerned with television engineering or an allied technology. It is expected that the award will be made to someone between 21 and 30 years of age, and the successful applicant will be known as the Baird Scholar. The scholarship is intended to assist the successful applicant in undertaking a period of investigation abroad of approximately 6-8 weeks. During this period some aspect of television, or an allied technology, will be investigated. Further information can be obtained from the Hon. Secretary of the Television Society, 166 Shaftesbury Avenue, London, W.C.2.

### Fishery Research Training Grants

THE Development Commissioners, in association with the Ministry of Agriculture, Fisheries and Food and the Department of Agriculture and Fisheries for Scotland, will award postgraduate training grants in fishery research, tenable from October 1. The grants are intended to enable the selected candidates to undergo a specified course of training to fit them for the investigation of problems in marine or freshwater science. Candidates must be British subjects and should be honours graduates in science from a British university, or possess equivalent qualifications. Further information and forms of application can be obtained from the Secretary, Development Commission, 3 Dean's Yard, Westminster, London, S.W.1.

### University News:

THE following lectureships have been announced: Dr. A. A. Rutherford (agricultural biometrics); Dr. A. McDowell Mercer (pure mathematics).

#### Belfast

#### London

THE following appointments have been announced: *Professorships*, Dr. K. W. S. Sing (chemistry, tenable at Brunel College). *Readerships*, Dr. D. M. Matthews (chemical pathology, tenable at Westminster Medical School); Dr. J. E. Ffowes Williams (applied mathematics, tenable at the Imperial College of Science and Technology). The following titles have been conferred: *Professorships*, Dr. M. E. Fisher (physics, at King's College); Dr. J. B. E. Baker (pharmacology, at Charing Cross Hospital Medical School); Dr. J. S. Weiner (environmental physiology, at the London School of Hygiene and Tropical Medicine). *Readerships*, Dr. J. S. L. Leach (physical metallurgy, at the Imperial College of Science and Technology); Dr. R. D. Milne (aeronautical engineering, at Queen Mary College); Dr. N. McA. Sayers (electrical engineering applied to medicine, at the Imperial College of Science and Technology).

### Royal Holloway College

IN October 1965 the Royal Holloway College will admit men as undergraduates for the first time, thereby instituting a process of expansion which is expected to more than double its size by 1967. An illustrated brochure issued by the College outlines the scope of its faculties of arts and science and sketches the proposed developments in botany, chemistry, physics and zoology (Pp. 24. Englefield Green: Royal Holloway College, 1964). By October 1967 the expansion is planned to create a mainly residential college of 1,000 students with men and women in equal numbers.

#### Swansea

DR. F. T. BARWELL, director of electrical research, British Railways Board, has been appointed professor of mechanical engineering in succession to Prof. R. H. Macmillan.

### Announcements

DR. M. TALWANI, a senior scientist at the Lamo Geological Observatory, Columbia University, has been selected by the Indian Geophysical Union as the first recipient of its newly created Krishnan Medal, for outstanding work in the field of marine geophysics.

THE Organization of the Felt Industry in Europe invites young people in the employ of members of the Organization, and of firms in the paper-making and allied industries and students in universities, colleges and other educational institutions, to submit technical or scientific papers for consideration for the annual awards of the Organization. Further information can be obtained from the General Secretariat, OFE, Raamweg 13, The Hague.

H. J. HEINZ COMPANY, LTD., and the National Vegetable Research Station Association have each agreed to finance a second postgraduate scholarship, tenable at the National Vegetable Research Station as from October 1. The purpose of the scholarships is to enable graduate students to pursue further studies and obtain training in one of the following subjects: chemistry; plant physiology; irrigation; plant pathology; ecology and control of weeds; biometry. Further information can be obtained from the Secretary, Vegetable Research Station, Wellesbourne, Warwick. The latest date for receipt of applications is April 30.

A. DOUGLAS CO., LTD., is to act as sole British importer of the multi-head linear dividing machine manufactured by V. E. B. Feinmess, of Dresden. This machine is capable of dividing 24 specimens simultaneously. The gradations may be applied to work-pieces over a wide range of materials, such as steel, aluminium, brass, plastics and glass. A wide range of literature covers a variety of dividing machines, including circular and linear machines of high precision, also universal and multi-head machines of the production type, etching pantograph and number engraving pantograph. Further information can be obtained from A. Douglas Co., Ltd., Lincoln Road, Cressex Industrial Estate, High Wycombe, Bucks.

AN ordinary meeting of the North of England Section of the Society for Analytical Chemistry will be held in Durham on March 12. Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

THE tenth annual general meeting of the Midlands Section of the Society for Analytical Chemistry will be held in the University of Birmingham on March 11. Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

THE Palynological Society of India was inaugurated on January 5 by Prof. T. S. Mahabale (Poona University) during the 51-52 session of the Indian Science Congress. The following have been elected to the Executive Council of the Society: *President*, Prof. K. N. Kaul; *Vice Presidents*, Prof. A. R. Rao and Prof. A. K. Ghosh; *General Secretary-cum-Treasurer*, Dr. P. K. K. Nai; *Councillors*, Dr. K. Biswas, Prof. U. N. Chatterjee, Dr. G. B. Deodkar, Prof. T. S. Mahabale, Dr. D. D. Panigrahy, Prof. V. Puri, Dr. Bhoj-Raj, Dr. J. Sen, Mr. B. D. Sharma, Dr. D. N. Shivepuri, and Dr. M. S. Swaminathan. Further information can be obtained from Dr. P. K. K. Nai, National Botanic Gardens, Lucknow.

CORRIGENDUM. In Fig. 1 of the article entitled "A Antifouling and Anti-corrosion System", by B. Wise (*Nature*, 203, 1132; 1964), a discrepancy occurs in the "scale drawing". The true boundary between the "hydrophobic layer" and the "rest" was omitted; to correct this a line needs to be added parallel to and 8 mm to the left of the line labelled "rest".

## THE SCIENCE AND TECHNOLOGY BILL

WHEN the Science and Technology Bill was considered in Committee in the House of Commons on January 20, several amendments were proposed to the clause relating to the Research Councils. However, these were withdrawn on receiving satisfactory explanations from Mr. M. Stewart, then Secretary of State for Education and Science. Mr. D. Price had raised the question of the functions of these Councils and the choice of priorities in the light of the final report of the Advisory Council on Scientific Policy. Mr. Stewart agreed as to the importance of priorities in research and said that besides their responsibility for the execution of research the Research Councils were responsible for the choice of priorities within their fields. The new Council on Scientific Policy was responsible for advising the Government on the choice of priorities in the allocation of funds between the various fields represented by the Research Councils and elsewhere. Mr. Price raised a further question regarding the Natural Environment Research Council, and while he and other speakers welcomed the establishment of this Council, there was some concern as to whether its responsibilities were wide enough in regard to water. Some natural resources are the responsibility of other Ministries: gas and coal (Ministry of Power), sand and gravel (Ministry of Public Buildings and Works), etc. Mr. Stewart did not entirely dispel these fears, and admitted that soil surveys fell within the scope of the Agricultural Research Council. Oceanographic research would come within the sphere of the Natural Resources Research Council, which would take over existing interests in the National Institute of Oceanography.

A further amendment advocated the establishment of a Work Study Research Council. However, while agreeing as to the importance of this subject, Mr. Stewart deprecated any such decision pending the report of the Heyworth Committee on the Social Sciences, which might well point to the creation of a research council for the social sciences. The question of space research and a Space Research Council was also raised by several members in this interesting and well-informed debate, but both Mr. J. Hogg and Mr. Stewart, supported by other members, resisted the argument. While agreeing that space research was an essential human effort at the present time, they

maintained that the size of the British effort in that field was a matter for the Council on Scientific Policy and the Government and not something to be written into the Bill.

Reference was also made to the position of the National Research Development Corporation. While the Corporation welcomed, in its annual report for 1963-64 (published a few days after the debate), the statement made by the previous Government in July that it had been decided to seek powers to extend the scope and scale of its work so that it would be able to contribute more effectively to industrial innovation and development, Mr. Stewart did not refer to the legislation then promised for this purpose, including provision for a modification and extension of the financial and other conditions under which the Corporation operates.

Sir Edward Appleton's opening address, "The Relationship between Science and Administration", in the Scottish Office Course on Science, given in Edinburgh on January 8, provides an interesting gloss on the debate. After reviewing the development of the relations between science and Government in Britain from the formation of the Royal Society down to the establishment of the National Physical Laboratory in 1900, and the foundation of the Department of Scientific and Industrial Research with its Advisory Council, Sir Edward referred to the Science and Technology Bill. He referred also to the Haldane Report on the machinery of government and particularly its doctrine that research and enquiry should be carried out under a Minister without specific departmental duties, although in close touch with Departments concerned with the activities under investigation. Sir Edward commented that thirty years ago potential user departments were often not well qualified to appreciate when scientific advice could be helpful, nor to estimate its value when given. It would seem that even to-day he has misgivings about the Road Research Laboratory being transferred to the Ministry of Transport. He is also uneasy as to the implications of appointing personal scientific advisers to a Minister, believing that this device contributed to difficulties during the War. It is not clear whether or not this criticism relates to the growing practice of appointing chief scientific officers of high status in Ministries concerned with scientific and technical matters.

## NORTH SEA LICENCES FOR THE GAS COUNCIL-AMOCO GROUP

THE Gas Council-Amoco Group comprises the Gas Council, Amoco U.K. Petroleum Ltd. (a subsidiary of American International Oil Company), Amerada Exploration Ltd. (a subsidiary of Amerada Petroleum Corporation), and Texas Eastern (U.K.) Ltd., all British corporations, and was formed early in 1963. According to a report issued on behalf of the Group (*P.R.* 6685, September 1964, The Gas Council, 1, Grosvenor Place, London, S.W.1), five licences to drill for oil and natural gas in the North Sea have been granted to the Group, which has already completed extensive seismic survey work within its now designated area of 3,600 square miles of sea; this area is divided into 36 blocks, with loci scattered over an area ranging from Peterhead in the north of Scotland down to offshore of the Norfolk coast.

Production licences cost £6,250 per block for an initial period of six years, with an option for a further 40 years "... on no more than half the area awarded to the Group at annual sums rising from £10,000 to £72,500 per block".

It is anticipated that drilling operations will begin in 1965. In this connexion it has recently been reported in the national Press that the Group has placed an order with John Brown and Co., Ltd., of Glasgow, worth £2.5 million, for a drilling platform, to operate in the North Sea area. The published particulars of this particular platform are impressive. It will stand on latticed steel legs 387 ft. high and will be built to accommodate 50 operatives; it will include a helicopter deck to facilitate communications with on-shore bases; it is designed to withstand winds of 115 m.p.h. and waves of 64 ft. These factors put this project in the class of super drilling platforms, one of the largest and most expensive structures so far conceived for offshore drilling for oil and gas. According to the report from the Group, it is considered unlikely that the rig, when in operation, will be able to drill more than two or three wells a year, because it is anticipated that completion depth could, at any one site, range to the 10,000 ft. mark, or even deeper.

A majority of the world's great oil and gas fields have been proved only after drilling several dry holes and expending large amounts of money; even a single field may require several holes to be drilled before it is proved a commercial proposition. The hazards of offshore drilling, where there is known continuity of seaward extension of land-based oilfields, are often formidable; in the case of the North Sea, the hazards, and consequently the risk of failure, are greatly increased because of lack of

such continuity. The North Sea, at least in so far as British licences at present extend, is a relatively unknown environment so far as oil and gas potentialities are concerned; to this extent optimism for the outcome, not only of the Gas Council-Amoco Group's enterprise, but equally for the pioneer efforts of other major oil interests now actively engaged in the search, must necessarily be tempered with caution and restraint; this is implicit in the report herein considered.

## ELECTRON MICROSCOPY OF GRAPHITIC CRYSTALLITES IN *Meta-ANTHRACITE*

By J. T. McCARTNEY and Dr. S. ERGUN

Pittsburgh Coal Research Center, Bureau of Mines, U.S. Department of the Interior, Pittsburgh, Pa.

**E**LECTRON microscopy of coals and coal components has been greatly facilitated by development of a technique for cutting ultra-thin sections (500–2000 Å) of these materials by microtomy with a diamond knife<sup>1–5</sup>. Granular structures as small as 100 Å and pores of the order of 20–50 Å have been reportedly observed in some of these investigations. Results of recent investigations of various coal components have been described elsewhere<sup>6</sup>.

Of special interest among these were observations of an apparent vitrain band in a *meta-anthracite* from Leoben, Austria. Fig. 1 shows a typical electron micrograph of an ultra-thin section of this material. Although these sections appeared to be continuous, the micrograph reveals a jumble of thin platelets interspersed with many holes. Many of the platelets are nearly parallel to the plane of the micrograph, and their oval or polygonal outlines can be traced. Some have a roughly hexagonal shape. Both X-ray and electron diffraction patterns of this material have shown most of the characteristic sharp lines of graphite<sup>7,8</sup>. The latter pattern is shown in Fig. 2. The rings, in order from the centre, are identifiable with the following reflexions of graphite: (002), (100–101 doublet), (004), (103) (weak), (110), (112), (201), (114), (121), (300), and (220). Estimations of crystallite size from measurements of line broadening in the X-ray patterns have yielded a value of 800 Å for this coal.

Measurements of diameters of about a dozen clearly defined platelets in electron micrographs resulted in an average diameter of about 800 Å. It is evident that the platelets are crystallites of graphite that have formed and grown from aromatic layer clusters during metamorphosis of this *meta-anthracite*.

Fig. 2. Electron diffraction pattern of the section of Fig. 1

Fig. 1. Electron micrograph of an ultra-thin section of an apparent vitrain band in a *meta-anthracite* from Leoben, Austria. ( $\times 93,750$ ). (Unoriented section)

Fig. 3. Electron micrograph of a section of Leoben *meta-anthracite* cut parallel to the bedding. ( $\times 45,000$ )

To investigate the probable orientation of the crystallites with respect to the bedding planes, particles from the *meta*-anthracite vitrain band were embedded so that ultra-thin sections could be cut parallel and perpendicular to the bedding. Fig. 3 is a micrograph of a parallel section. Although the crystallite structures are not so prominent here, a general orientation of rounded platelets parallel to the film plane is evident. This is substantiated by an electron diffraction pattern of this section, shown in Fig. 4. The (002) ring is very weak, not nearly so strong as in Fig. 2, and the (004) reflexion is not detectable. Such decreased intensity of the (00 $l$ ) reflexions would be expected when the incident electron beam is more or less perpendicular to the diffracting planes.

Fig. 5 shows a section cut perpendicular to the bedding. An impression of layers of crystallites roughly perpendicular to the section is not difficult to conceive. Fig. 6, which is a diffraction pattern of this section, substantiates this conception. The rings show definite orientation effects; the accentuated arcs of the (002) and (004) rings are nearly parallel to the layer lines of Fig. 5, while those of the (100) and (110) rings are roughly perpendicular to these lines (Figs. 5 and 6 are shown in the same relative

Fig. 4. Electron diffraction pattern of the section of Fig. 3

Fig. 5. Electron micrograph of a section of Leoben *meta*-anthracite cut perpendicular to the bedding. ( $\times 45,000$ )

Fig. 6. Electron diffraction pattern of the section of Fig. 5

Fig. 7. Electron diffraction pattern of the section of Fig. 8

Fig. 8. Electron micrograph showing a relatively large single crystal of graphite in the Leoben *meta*-anthracite. ( $\times 18,750$ )

orientation). Since the (002) and (004) reflexions are due to interlayer spacings and the (100) and (110) are the result of in-plane atom distances, the oriented patterns are consistent with the foregoing interpretation.

During traversal of the sections while viewing the diffraction patterns, spot patterns characteristic of single crystals were often seen. These were largely attributable to mineral matter. However, in some instances, accentuated spots were seen on the graphite rings. Such a pattern is shown in Fig. 7. Six regularly spaced spots, in addition to other random ones, can be seen on both the (100) and (110) rings, with the spots on the two rings at alternate  $30^\circ$  angles. Observations of the area contributing to this pattern disclosed the large crystallite shown in Fig. 8. This crystallite, of the order of  $3\mu$  in diameter, is much larger than the average throughout this material, but a few of this size have been observed. The other, much

smaller crystallites contribute to the random spots and the nearly continuous ring.

The foregoing material presents direct evidence of the development of three-dimensional graphite crystallinity in *meta*-anthracite and the ordering of the crystallites in layer planes parallel to the bedding.

## THERMAL ANOMALIES ON THE TOTALLY ECLIPSED MOON OF DECEMBER 19, 1964

By J. M. SAARI and R. W. SHORTHILL

Boeing Scientific Research Laboratories, Seattle, Washington

RECENT infra-red measurements on small portions of the lunar disk made during eclipses<sup>1,2</sup> and during the lunar night<sup>3,4</sup> have revealed prominent thermal anomalies on ray craters, and lesser anomalies in other areas. A survey of the entire lunar disk is needed to determine the thermal homogeneity of the surface. While such a survey is possible for the dark side of the Moon, the low temperatures there require a slow scanning rate and observations over many nights. During a total lunar eclipse, however, the surface cools for only a short period, and its substantially higher temperature allows rapid scanning during totality.

In 1962 we developed a rapid scan system for mapping the Moon thermally and photometrically under illumination, using the 60-in. telescope at Mount Wilson<sup>4</sup>. The scan system was modified for use on the 74-in. Kottamia telescope of the Helwan Observatory in Egypt for observations during the total lunar eclipse of December 19, 1964. Using a mercury-doped germanium detector cooled to liquid neon temperature, we were able to scan the entire disk in 16 min at 10" arc resolution with approximately 200 successive traverses. Four scans were made on the full Moon before the eclipse began, four during the first penumbral phase, three during totality, and one during the second penumbral phase. These data were recorded on magnetic tape and are now being reduced on a 7094 computer.

A great amount of detail was revealed by chart recordings made during the experiment and is the basis for this preliminary report. As expected, prominent anomalies were found on the major ray craters Tycho, Copernicus, Aristarchus, Aristoteles, Proclus, Theophilus, Langrenus and Stevinus. For example, Fig. 1 is a tracing of the infra-red signal obtained on a traverse through Tycho, an outstanding thermal anomaly on the eclipsed Moon. Preliminary calculations indicate that the maximum temperature on Tycho is 226° K and the environ temperature 178° K, a difference of 48° K. On this traverse three peaks in the signal over Tycho may correspond to the rims and the central peak.

Perhaps the most surprising result of the experiment was the discovery of hundreds of localized thermal anomalies or 'hot spots' on the surface of the Moon besides those associated with the major ray craters. An example in Fig. 1 is the 'spike' in the signal near Tycho, tentatively identified with Heinsius A. Other examples of hot spots are seen in Fig. 2, where seven spikes in the signal correspond to locations in Mare Tranquillitatis and Mare Foecunditatis and on the edges of Mare Imbrium and Mare Serenitatis. The largest spike on the chart recordings, comparable to the signal from Tycho, was observed from the crater Dawes.

The positions of 300 of the more conspicuous hot spots are plotted in Fig. 3, where the boundaries between the seas and continental areas are indicated. The distribution of these anomalies is not uniform on the disk; for

example, a great number are found in Mare Tranquillitatis and relatively few in the continental area between Tycho and Theophilus. Many hot spots can be identified with the small ray craters which appear as white spots on the full Moon; these youthful features probably are thermally anomalous, as are the major ray craters, by reason of their denser and/or rougher surfaces. Some hot spots, however, are not associated with small ray craters; accurate positioning will be the first step in seeking an interpretation for these anomalies.

Another important result is the discovery of thermal enhancements over extended regions of the seas as shown in Fig. 1. Some of these extended enhancements are plotted in Fig. 3 as lines along the traverse direction. All of Mare Humorum appears higher in temperature than its environs, while only parts of Oceanus Procellarum, Mare Imbrium, and Mare Frigoris are elevated. Extended enhancements are also found in Mare Tranquillitatis and Mare Foecunditatis as shown in Fig. 2.

The significance of these results will become clearer after contour maps are plotted and cooling curves for specific areas of interest are constructed. The observed thermal anomalies will be plotted on maps of the lunar disk and compared with surface features. The inter-

Fig. 1. Tracing of the infra-red signal obtained on traverse number 81 during the third scan in totality of the December 19, 1964, total lunar eclipse. The scan began at 2h 55-0m U.T. and ended at 3h 10-4m U.T.

Fig. 2. Tracing of the infra-red signal on traverse 134 during the third scan in totality

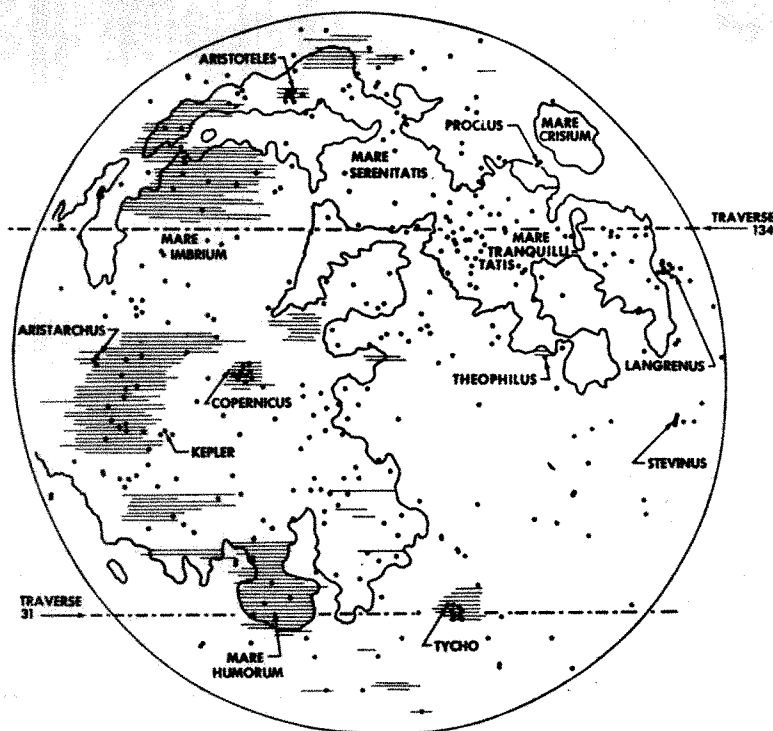

Fig. 3. Positions of 'spikes' in the infra-red signal (indicated by dots) obtained during the third scan in totality. Some of the extended thermal enhancements are indicated by lines in the traverse direction (see text). Traverses 31 and 134 are indicated by dot-dash lines

pretation of the results can then be made with respect to theoretical cooling curves and experimental data such as albedo, colour contrasts, stratigraphy, radar and infra-red measurements through a lunation.

We thank Prof. A. H. Samaha, director of the Helwan Observatory, for generous allowance of observing time on the 74-in. reflector at Kottamia; Dr. M. K. Aly, associate director, for collaboration at the telescope; and G. K. Bruce for assistance in carrying out the measurements.

Transport of the equipment was made possible through the co-operation of Dr. J. W. Salisbury, chief of Lunar-Planetary Research, U.S. Air Force Cambridge Research Laboratories, under contract AF19(628)-4371.

## SOME ELEMENTARY PROCESSES IN RADIATION- AND PHOTO-CHEMISTRY REVEALED BY ELECTRON SPIN RESONANCE

By DR. P. B. AYSCOUGH, R. G. COLLINS and PROF. F. S. DANTON, F.R.S.

Department of Physical Chemistry, University of Leeds

**E**LECTRONS may be generated at a uniform rate in liquids either by ionization of solvent molecules caused by the close passage of fast charged particles, for example, by irradiation with  $\alpha$ -,  $\beta$ - or  $\gamma$ -rays, or by photo-detachment from reducing solutes. Typical primary processes in aqueous systems are (1) and (2) below. In sufficiently polar media the electron may become solvated and persist long enough to establish its equilibrium ion-atmosphere so that when it reacts with a negatively or positively charged species the reaction is accelerated or decelerated by increases of ionic strength according to the Brønsted-Bjerrum equation<sup>1</sup>. The products of reaction of an electron with a solute having an even number of electrons must include a free radical the nature of which is usually inferred from the accompanying stable products, for example, nitrogen in reaction (3). Direct spectroscopic observation of such reactive species is only possible in fluid systems if their concentrations can be greatly increased by the techniques of pulse radiolysis<sup>2</sup> or flash photolysis<sup>3</sup> and provided they possess distinct, strong absorption bands in an accessible region. In this way it

has also been shown that many of the bimolecular reactions are diffusion controlled ( $k \approx 10^{10} \text{ M}^{-1} \text{ s}^{-1}$ ) and might therefore be expected to occur even at low temperatures. If a rigid medium is used the solute and the free radical product of its reaction with an electron will be immobilized so that the optical and electron spin resonance spectrum of the latter can be obtained. For the electron to react with the immobile solute the electron must be able to move from its point of origin through the medium. This is possible because as it is first formed the electron has energy considerably in excess of thermal levels.

In radiation chemistry this energy is typically about 10 eV and the electron can move distances about 10–100 Å before it is thermalized: in photochemistry the energy is about 1 eV and the distance is presumed to be shorter. If there is a solute lying in the path of the electron, reaction may occur. If no solute is present the electron may either continue its travel until it encounters a positive ion resulting from the primary act, or it may reach a region in the solid where the molecules are so oriented as to form a potential well which can bind a thermal electron. We shall refer to such an immobile electron in a solid as a 'trapped' electron denoted by  $e_t^-$  to distinguish it from the mobile solvated electron formed in a liquid and denoted, in the case of aqueous systems, by  $e_{aq}^-$ . Clearly the density of traps will be lowest in crystalline solids and higher in glasses and crystals containing anion vacancies. If a solute is present in the glass in concentration comparable with the trap density it will compete with the traps for capture of the electron. This competition is not disadvantageous to the investigation of solute-electron reactions because in all cases the trapped electron can be remobilized by absorption of light according to reaction (4). The electron,  $e_m^-$ , may either be retrapped at another site or be captured by a solute so that illumination causes the physical traps to be depleted by transfer of electrons to the solute molecules. Moreover, since a rise in temperature increases the possibility of rotation of molecules of the matrix, movement of electrons and free radicals through the matrix can be thermally induced and much can be learnt about this movement from an examination of the effect of step-wise temperature increases on the optical and electron spin resonance spectra of irradiated glasses.

This article describes the electron spin resonance spectra of various odd electron species produced by  $\gamma$ -rays or light and trapped in various glassy matrices at 77° K. It should be noted that always in radiation chemical, and sometimes in photochemical, generation of the electron another free-radical species must be formed. In radiation chemistry the molecular ion produced in the primary ionization generally reacts very rapidly with a neighbouring molecule in a proton-transfer reaction, for example, reaction (5) in the case of aqueous systems. To the extent that in photochemical systems the other species formed in the photo-detachment process is often relatively stable, these systems are often simpler to interpret than the radiation-chemical ones.

**Aqueous alkaline glasses.**  $\gamma$ -Irradiated alkaline glasses (> 1 N alkali) have been investigated extensively by Schulte-Frohlinde *et al.*<sup>4</sup> and by Erbov, Pikaev, Glazunov and Spitsyn<sup>5</sup>. In an 8 N NaOH glass  $e_t^-$  has an intense optical spectrum ( $\lambda_{max} = 5860$  Å,  $G_{e_{max}} = 3.7 \times 10^4$  M<sup>-1</sup> cm<sup>-1</sup>) and an electron spin resonance signal consisting of a single narrow line at  $g = 2.002-3$  (Fig. 1). A broad electron spin resonance peak at  $g = 2.04$  has been attributed to  $O_t^-$ . Unlike earlier workers, we find that when the irradiated glass is warmed to 150° K for a few minutes or is illuminated with visible light, the initial spectrum, attributed to  $e_t^-$ ,  $O_t^-$  and  $\dot{O}H$ , changes in such a manner as to indicate that the  $O_t^-$  and  $e_t^-$  disappear together and that only  $\dot{O}H$  remains (Fig. 1 and ref. 6). Thus the suggestion<sup>4</sup> that reaction (6) occurs on warming is not supported, although this reaction may be responsible for the  $O_t^-$  produced during the  $\gamma$ -irradiation. On the other hand, a reaction leading to the conversion of  $O_t^-$  to  $\dot{O}H$  (equation (7)) would explain our observations. Attempts to obtain the spectrum of  $\dot{O}H$  in an alkaline system by photolysing  $H_2O_2$  in deaerated 8 N NaOH

Fig. 1. Electron spin resonance spectra of  $\gamma$ -irradiated 8 N NaOH glass at 77° K. (a) Immediately after irradiation; (b) after illumination with visible light

have not been successful, the only species formed being  $O_2^-$  or  $\dot{H}O_2$  (ref. 6) which appears before photolysis and which is presumed to be an intermediate in the rapid chain decomposition of  $H_2O_2$  which is observed.

Electron scavengers, added before irradiation, all reduce the  $e_t^-$  signal and replace it partially or completely by that of a neutral radical  $R\cdot$  formed in the dissociative electron capture process (8) where  $RX = CH_3Cl$ ,  $C_2H_5Cl$ ,  $ClCH_2COOH$ ,  $FCH_2COOH$ ,  $CH_2OHCOOH$ ,  $CH_3CN$ . The behaviour of a glass containing approximately  $3 \times 10^{-2}$  M  $CH_3Cl$  is typical<sup>10</sup>. The initial spectrum clearly indicates the presence of  $e_t^-$  and methyl radicals, the latter increasing very markedly on warming to 130° K or illuminating with visible light at 77° K (Figs. 2 and 3).

The effect of adding nitrous oxide (at 5 atmosphere pressure in order to increase solubility) is to increase the  $O_t^-/e_t^-$  ratio because of the occurrence of reaction (9).  $N_2O^-$  is not observed. On photobleaching, some of the mobile electrons react with  $N_2O$  so that the  $O_t^-$  increase slightly and some react with  $\dot{O}H$ , the signal from which is thereby diminished. Conversely, the addition of an  $\dot{O}H$  scavenger such as  $10^{-2}$  M glycerol before irradiation decreases the relative yield of  $\dot{O}H$ , as expected, and after photobleaching the residual  $\dot{O}H$  is an order of magnitude less than that observed in the pure samples.

The  $e_t^-$  peak and blue coloration are also seen when 8 N NaOH containing  $10^{-4}$  M  $K_4Fe(CN)_6$  is irradiated with light of wave-length 2537 Å. In this case no  $O_t^-$  and no  $\dot{O}H$  is seen (Fig. 3a). The addition of electron scavenger to these glasses reduces the  $e_t^-$  peak and replaces it by that of the appropriate radical (reaction (8)) confirming the identity of the reducing species and the reality of reaction (2c) in the system (Fig. 3b). Photo-ejection of an electron from  $I^-$ ,  $OH^-$  and  $N_3^-$ , which occurs readily in fluid media, has not been observed in alkaline glasses using light of wave-length 2537 Å or 2230 Å, possibly due to the marked blue shift of electron detachment spectra caused by a 200 deg. temperature drop<sup>7</sup>.

**Aqueous acid glasses.** In  $\gamma$ -irradiated glasses of 6 N  $H_2SO_4$  or in ultra-violet-irradiated glasses containin

Fig. 2. Electron spin resonance spectra of  $\gamma$ -irradiated 8 N NaOH glass containing  $3 \times 10^{-4}$  M  $\text{CH}_2\text{Cl}$  at  $77^\circ \text{K}$ . (a) Immediately after irradiation; (b) after warming to  $150^\circ \text{K}$  for 5 min

Fig. 3. (a) Electron spin resonance spectrum of NaOH glass containing  $10^{-4}$  M  $\text{K}_2\text{Fe}(\text{CN})_6$ , after illumination with light of wave-length  $2537 \text{ Å}$ ; (b) as (3a) above, with addition of  $\text{CH}_2\text{ClCOOH}$  before irradiation

$0.4 \text{ M Fe}^{2+}$ , no blue colour develops and no electron spin resonance signal attributable to  $e^-$  is observed. Instead there is a strong signal from trapped hydrogen atoms<sup>8,9</sup> which are formed by reaction of the electron with OH groups on the  $\text{SO}_2$  polymer chains according to (10). In addition, there is a large asymmetric peak at  $g = 2$  which appears to be associated with the acid residue and is probably formed by reaction of  $\text{H}_2\text{O}^+$  with  $-(\text{SO}_3)_n\text{O}_2\text{OH}$  in a manner analogous to reaction (5) (Fig. 4a). The paramagnetic centre probably has the structure  $-\text{SO}_2-\dot{\text{O}}$ . If nitrous oxide is added before irradiation the concentration of H atoms is reduced to an extent which is closely related to the amount of additive. The addition of  $\text{ClCH}_2\text{COOH}$  results in the formation of  $\text{H}_2\text{COOH}$ , identified by its electron spin resonance spectrum<sup>10</sup>, similar to that shown in Fig. 3b. This evidence, together with the kinetic evidence presented elsewhere<sup>10</sup>, suggests that  $e^-$  is a precursor of H in these systems, and

that both  $\text{N}_2\text{O}$  and  $\text{ClCH}_2\text{COOH}$  can compete successfully with  $\text{H}_2\text{O}^+$  and  $-\text{SO}_2\text{OH}$  for the mobile electrons at concentrations of  $10^{-3} \text{ M}$  or less.

However, these systems are very much more complicated than the alkaline glasses as may be adduced from their behaviour on warming. The hydrogen atoms disappear by a second-order process at a measurable rate at  $85^\circ \text{K}$  and very rapidly at  $95^\circ \text{K}$ , while little change occurs in the central peak, attributed to  $-\text{SO}_2-\dot{\text{O}}$  (ref. 9). However, above  $100^\circ \text{K}$  this peak increases very markedly in size, reaching a maximum height (when measured at  $77^\circ \text{K}$ ) five or six times that observed initially. This maximum occurs after warming to  $120^\circ$ – $125^\circ \text{K}$ ; further warming causes a diminution until the signal disappears after warming to about  $150^\circ \text{K}$ . During these changes the signal becomes almost symmetrical and develops small shoulders. Furthermore, in samples containing nitrous oxide, additional fine structure centred at  $g = 2$  is observed (Fig. 4b). This appears at about  $110^\circ \text{K}$  and disappears at  $130^\circ \text{K}$ . Finally, ultra-violet irradiation at  $77^\circ \text{K}$  of samples which have been warmed above  $100^\circ \text{K}$  causes a reduction in size of the central peak which may be restored by warming to the maximum temperature reached during the previous warm-up.

These observations, while not fully understood, suggest the presence of another form of electron trap from which the electron may be ejected by relaxation of the matrix. This trap might be a point at which the electron could interact with oxygen atoms from two or more  $-(\text{SO}_2-\text{O})_n$  chains, the resulting anisotropy rendering the absorption line too broad for detection. Mobility might then be restored to the electron by thermal relaxation, leaving an  $-\text{SO}_2-\dot{\text{O}}$  radical. The temporary appearance of hyperfine structure in samples containing nitrous oxide must be similarly associated with the formation of  $\text{N}_2\text{O}^-$  by a species not observed initially at  $77^\circ \text{K}$ . ( $\gamma$ -Irradiation of pure  $\text{N}_2\text{O}$  gives a weak triplet having line separation about 6 gauss and line-width about 2 gauss, very similar to that of nitrogen atoms trapped in solid nitrogen at  $4^\circ \text{K}$ <sup>11</sup>). More detailed quantitative investigations are needed before this problem can be resolved.

*Non-aqueous glasses* (methanol,  $\alpha$ -methyl tetrahydrofuran and olefines). The behaviour of these non-aqueous glasses is in many ways analogous to that of the alkaline aqueous glasses. For example,  $\gamma$ -irradiation of a methanol glass at  $77^\circ \text{K}$  produced electron spin resonance and optical spectra which indicate the presence of trapped

Fig. 4. Electron spin resonance spectrum of  $\gamma$ -irradiated 6 N  $\text{H}_2\text{SO}_4$  containing  $\text{N}_2\text{O}$  at 1 atm. pressure. (a) Immediately after irradiation at  $77^\circ \text{K}$ ; (b) after warming to about  $130^\circ \text{K}$

electrons and  $\dot{\text{C}}\text{H}_2\text{OH}$  radicals<sup>12,13</sup>. The sequence of reactions is summarized in equations (11) and (12):

The trapped electrons have an optical absorption band with  $\lambda_{\text{max}} = 5330 \text{ \AA}$  to be compared with  $\lambda_{\text{max}} = 5400 \text{ \AA}$  for  $e_t^-$  in alkaline methanolic glass and  $\lambda_{\text{max}} = 6500 \text{ \AA}$  for the solvated electron in methanol<sup>14,15</sup>. Similarly,  $\cdot\text{CH}_2\text{OH}$  has an absorption maximum at a much shorter wavelength in the glass at  $77^\circ \text{K}$  than in the liquid at room temperature<sup>15</sup>. The electron spin resonance spectrum of  $e_t^-$  is much broader than that observed in the alkaline glasses and may have hyperfine structure. Unfortunately, the insolubility of  $\text{K}_4\text{Fe}(\text{CN})_6$  precluded the use of reaction (2c) to obtain the spectrum of  $e_t^-$  in the absence of  $\dot{\text{C}}\text{H}_2\text{OH}$  radicals, so this interpretation is tentative. However, hyperfine structure has been observed in electrons trapped in neutral aqueous glasses prepared by the reaction of sodium with ice at  $77^\circ \text{K}$  (ref. 16). Some confirmation of this interpretation is provided by the observation that illumination of the  $\gamma$ -irradiated methanol glass with green light approximately doubles the size of the triplet of  $\dot{\text{C}}\text{H}_2\text{OH}$  and reduces that of an underlying peak but the total peak area remains the same. This effect is attributed<sup>15</sup> to photo-detachment of  $e^-$  in reaction (4) followed ultimately by reaction (13) in which the hydrogen atom is 'hot' and therefore reacts immediately with a neighbouring methanol molecule according to equation (14).

This effect is quite different from that of irradiation with ultra-violet light which causes decomposition of  $\dot{\text{C}}\text{H}_2\text{OH}$  (ref. 17) and of  $\dot{\text{C}}\text{HO}$  so that steady-state concentrations of  $\dot{\text{C}}\text{H}_2\text{OH}$  and  $\dot{\text{C}}\text{HO}$  are ultimately attained through the cycle of the following reactions<sup>17</sup>:

$\gamma$ -Irradiation of glasses made by rapidly cooling  $\alpha$ -methyltetrahydrofuran (MTHF) is known from Hamill's work<sup>18</sup> to result in the formation of  $e_t^-$  and the electron spin resonance spectrum shown in Fig. 5a has also been found<sup>19,20</sup>. The central peak, about 3 gauss wide, is believed to be associated with trapped electrons, since it shows the same thermal and photochemical relaxation pattern as the broad optical absorption based with  $\lambda_{\text{max}} = 12,500 \text{ \AA}$ . Both are destroyed by illumination with red light. The outer structure and the absorption at  $2500 \text{ \AA}$ , which are unaffected by illumination with red light<sup>15</sup>, may be assigned to the radical

in which two  $\beta$ -protons have hyperfine splittings of about 35 and 20 gauss, respectively, and the methyl protons about 20 gauss. The areas of these two features are comparable when observed under sufficiently low microwave power, and it is believed that the reactions involved are:

The addition of small quantities of naphthalene or carbon tetrachloride to MTHF before irradiation causes diminution of the  $e_t^-$  peak, and the appearance of feature corresponding to the attachment of  $e^-$  to the additive. In the case of naphthalene a structureless peak about 3 gauss wide is observed (the naphthalene monoanion). When carbon tetrachloride is added, an additional asymmetric peak at  $g = 2.02$  is seen (Fig. 5b). This probably indicates the presence of  $\text{CCl}_3$  formed by dissociation of  $\text{CCl}_4$ . The addition of nitrous oxide also reduces  $e_t^-$  but no additional spectrum is seen (Fig. 5c).

Olefines such as 2-methyl-butene-2 and hexene-2 which form transparent glasses at  $77^\circ \text{K}$ , also develop a weak blue coloration when  $\gamma$ -irradiated in the absence of light. It has been suggested<sup>21</sup> that the visible absorption in these systems indicates the presence of cationic species and that an absorption band in the infra-red corresponds to trapped electrons. We find that the electron spin resonance spectra of these olefines when examined in the absence of light consist of a narrow single peak about three gauss wide superimposed on the broad hyperfine spectrum of trapped alkyl radicals<sup>22</sup>. The singlet peak is very weak in 2-methyl-butene-2 but quite marked in hexene-2. When illuminated with visible light the blue colour disappears almost immediately, but the electron spin resonance singlet persists for about 5 min. Thus the photochemical relaxation of the optical absorption and the electron spin resonance signal follow different courses in contradistinction to the behaviour of the MTHF glasses. Although it is very likely that the electron spin singlet is caused by  $e_t^-$ , there is as yet no proof of this. These conclusions are in agreement with our earlier observations<sup>23</sup> on thermal annealing of *n*-hexadecene-1 in which it was suggested that the decrease in concentration of the trapped dimeric radical-cation was caused by the progressive release of a mobile species, presumably electrons, from traps of different energies.

Fig. 5. Electron spin resonance spectra of  $\gamma$ -irradiated  $\alpha$ -methyltetrahydrofuran at  $77^\circ \text{K}$ . (a) Immediately after irradiation; (b) as above, with addition of  $\text{CCl}_4$  before irradiation; (c) as above, with addition of  $\text{N}_2\text{O}$  before irradiation.

Fig. 6. Low-field hydrogen atom peak in  $\gamma$ -irradiated 6 N  $\text{H}_2\text{SO}_4$  at 77° K

**Matrix effects.** While the foregoing electron spin resonance data do not confirm the mechanisms already outlined here, they provide powerful support for the conclusions based on detailed analyses of the kinetics of the decompositions. It is significant that the basic reactions are very similar despite the widely different matrices. However, the differences in the spectra associated with the trapped electron need some comment. There has already been much speculation on the nature of the electron traps in alkaline glasses<sup>24,25</sup>, and there is increasing support for the view that the electron is trapped in an anion vacancy surrounded by water molecules, rather than in an expanded orbital of the cations as has been suggested for electrons in liquid ammonia. The line width (about 15 gauss in 8 N NaOH) is reduced to about 6 gauss on replacing  $\text{H}_2\text{O}$  by  $\text{D}_2\text{O}$ , so that some proton interaction is implied. The observation of proton interaction in neutral ice where the individual line width is only 2–3 gauss<sup>16</sup> and our observations on methanolic glasses support this view. The absence of such interaction in ethereal systems (for example, MTHF) and the long relaxation time probably indicate that the vacancy occupied by the electron lies between two MTHF rings and is too distant from the protons to give either an observable interaction or rapid relaxation. A further observation of some relevance here is that in some samples of 6 N  $\text{H}_2\text{SO}_4$  the hydrogen atom peaks appear as quintets or septets with peak separation of 7 gauss and line width about 2 gauss (see Fig. 6), almost identical with the values quoted for the  $e_{\text{aq}}^-$  peak in ice. One is tempted, therefore, to suggest that the H atom traps have a very similar conformation, interacting weakly with four or six neighbouring protons. This

behaviour is not very reproducible, the H atom peaks sometimes appearing with satellites as reported by Livingston<sup>26</sup>. In glasses containing  $\text{Fe}^{2+}$  (and, of course,  $\text{Fe}^{3+}$ ) any such structure is obscured by the greater line width (7–8 gauss) presumably caused by the presence of a relatively high concentration of paramagnetic ions in the matrix.

We thank G. A. Salmon, C. G. Gopinathan, T. J. Kemp and J. Russell, of the University of Leeds, and J. Teply, of the Nuclear Research Institute of the Czechoslovak Academy of Sciences, for permission to quote some of their results prior to publication. We also thank the Rockefeller Foundation, the Department of Scientific and Industrial Research and the International Atomic Energy Agency for financial assistance in the form of capital grants and maintenance allowances.

## A COMMERCIAL SPECTROMETER MODIFIED FOR X-RAY SPECTROSCOPY OF THE LIGHT ELEMENTS

By PROF. RALPH W. G. WYCKOFF, For.Mem.R.S., and FRANKLIN D. DAVIDSON

Department of Physics, University of Arizona, Tucson, Arizona

CONVENTIONAL X-ray spectroscopy has been very successful in the analysis of elements heavier than silicon and has given results of limited accuracy and sensitivity for aluminium and magnesium. It has failed for lighter elements because of the low efficiency of the fluorescent excitation of their characteristic X-rays and because their very long wave-lengths could not be analysed in spectrometers built to deal with the harder radiations from heavier elements. Recent developments in ways to excite very soft X-rays and in techniques for their measurement now make it relatively easy to analyse for the lighter elements through boron [ $\lambda(K\alpha) = 67 \text{ \AA}$ ]. We describe here a simple modification of a commercial X-ray spectrometer which permits this extension.

The problem of low X-ray production by light elements can be met<sup>1,2</sup> by eliminating the window between the tube target and a 'fluorescing' sample; this will increase by as much as a thousand times the output of characteristic X-rays. Single crystals are not available with spacings great enough to reflect the X-rays from elements lighter than oxygen, but stacked monomolecular films of lead stearate or other fatty acid salts will act as very efficient gratings with  $2d$  spacings at least as large as 125 Å. The counter tubes ordinarily used will not record the X-rays in question because of absorption in their windows, but they are satisfactory when equipped with stretched polypropylene or even with thin collodion windows.

Fig. 1. Photograph of the Philips vacuum spectrometer arranged for soft X-ray measurements. The gas type X-ray tube is at B and the vacuum leak at A.

After having carried out extensive measurements with a spectrometer especially arranged for the examination of long X-rays, we have applied the X-ray source, grating and detector developed for this instrument to the commercially available Philips vacuum spectrometer to see how it would perform in this extension of X-ray spectroscopy. The gas type X-ray tube (B in Fig. 1), mounted in this Philips spectrometer, is an obvious modification of that recently described<sup>1</sup>; it is built round a casting for a standard FA-60 X-ray tube and fits as a direct replacement for such a tube. The target, which is exchangeable, is water cooled through the same leads which cool an FA-60. The power consumption of the gas tube for this work is so small (about 25 W) that no other water cooling is required. The sample is placed in one of the usual specimen holders from which the mylar has been removed and there is no window between it and the anode of the tube. For work with soft X-rays it is important that low voltages be used to minimize background due to white radiation. The standard, unmodified Philips power supply, operated at its lowest value between 10 and 15 kV, can be used for the analysis of elements heavier than fluorine, but for this element and those still lighter better results are obtained if the tube is operated in the region 5–10 kV. In view of the small power needed—in none of our experiments with this instrument has it exceeded 100 W—an inexpensive power supply has been adequate. The tube operates at a vacuum of about 20  $\mu$  and no difficulty has been experienced in creating a better vacuum than this throughout the apparatus with the Welch No. 1402 oil pump which routinely evacuates the spectrometer. For quantitative measurements of intensity it is obviously essential to have a constant X-ray output. This is readily obtainable by introducing a controlled air leak into the pumping system. It can be done with such a precision needle valve as the Whitey 22RS4-316 (purchased from Whitey Research Tool Co., 5525 Marshall Street, Oakland, 8, California), connected directly to the atmosphere, but we find it somewhat better to connect the valve to a buffer tank (an old butane bottle, for example) which is partially evacuated every day or two.

As an analysing 'crystal' a 130-layer<sup>3</sup> lead stearate (LS) grating is commonly used. Such a 'grating' is not difficult to prepare with a modified Langmuir trough. Analyses with greatly increased sensitivity can now be

made for silicon and aluminium with an ethylenediamine ditartrate (EDDT) crystal and for lighter elements with mica or potassium acid phthalate (KAP) crystals. If the stearate grating is to be used to measure the heavier of these light elements, this should be done in a higher order to avoid the high background at low angles of reflexion. An idea of the relative efficiencies of the three crystals and the stearate grating can be gained from the fact that the intensities of the first order  $K\alpha$  lines of aluminium are in the ratio 100 (EDDT): 27 (mica): 70 (KAP): 200 (LS). Intensities of the several orders of a spectral line from a typical LS grating are in the approximate ratio 100:19:12:3:2 for its first five orders. As we make them, such a grating is built up on a 1 in.  $\times$  3 in. microscope slide which can very simply replace the second crystal in the double crystal holder of the Philips spectrometer.

The flow proportional counter of the commercial instrument can be used as detector for the long wave-lengths with only a change of window. This window is, however, so large that it is customary to coat its inner surface with aluminium or carbon for stable operation. Such a coating increases unnecessarily the opacity of the stretched polypropylene; it can be avoided by facing the new window on the counter side with aluminium foil cut to cover all but an area of about 7 mm  $\times$  25 mm of the Soller slit. The P-10 (argon 90 per cent-methane 10 per cent) counter gas conventionally used in X-ray spectroscopy will record long X-rays; and the higher counter voltages required, up to about 1,900 V, are within the range of the circuit panel customarily used with this instrument.

Fig. 2 shows typical spectra obtained with the Philips spectrometer as modified above; backgrounds are low

Fig. 2. The  $K\alpha$  lines of boron, carbon and oxygen as recorded with the spectrometer of Fig. 1. All spectra were taken with 25 W through the tube. For carbon the sample was compressed graphite. The spectra for boron and oxygen at the right were obtained from pressed boric acid

Table 1. OBSERVED PEAK HEIGHTS (IN C/S/W) OF LS SPECTRA OF LIGHT ELEMENTS

Element	Spectral order	
	First	Second
Aluminium	—	400
Magnesium	—	394
Sodium (NaCl)	—	(292)
Fluorine (LiF)	(840)	(203)
Oxygen	(196)	(28)
Nitrogen	(13)	—
Carbon	1,100	—
Boron	(480)	—

and peak-to-background ratios satisfactory. Table 1 gives the observed efficiencies of  $K\alpha$  lines (in c/s/W of energy through the X-ray tube) measured for several elements. Numbers in parentheses are observed values adjusted for 100 per cent content of the element but not for absorption. They have no absolute significance and depend on many factors including a tube voltage which will ordinarily be chosen to give the optimal peak-to-

background ratio for the elements being analysed. The intensities shown in the figure can easily be increased by raising the power through the tube, but they are sufficient to permit accurate analyses for small amounts of all the light elements except nitrogen. The low efficiency for nitrogen recorded in the table is due to the extreme absorption of its characteristic X-rays by the carbon of the counter window; this is a situation that will always prevail unless a suitable non-carbonaceous window material is found.

## SIZE EFFECT OF OXYGEN ANION ON PARTITION COEFFICIENTS

By DR. AKIMASA MASUDA

University of Tokyo, Tanashi-machi, Tokyo

MATSUI and I have attempted to evaluate the partition coefficients of elements for the process of crystallization of silicate melt, mainly basic<sup>1-5</sup>. It was the analysis<sup>4</sup> of abundance variation of lanthanides that stimulated us to undertake this series of investigations.

Hence, the partition coefficients were first obtained for lanthanides<sup>4,5</sup>. These values resulted from the interpretation that the partition coefficients of lanthanides, arranged in order of atomic number, formed an arithmetical progression.

In this connexion, furthermore, it was found<sup>6</sup> that the reciprocal of ionic radius rather than the ionic radius itself, of lanthanides, changed linearly with atomic number. (It must be added here that this finding is derived from a set of ionic radii given by Templeton and Dauben<sup>7</sup> for lanthanides. So far as the relative magnitude is concerned, their values for lanthanides are much more precise than those presented by Goldschmidt<sup>8</sup>, apart from the absolute scale.) Fig. 1 shows the relation between the partition coefficient obtained by me and the reciprocal of ionic radius. The correlating line in this diagram is intriguing in two respects<sup>6</sup>: the positions of the intersections of partition coefficients at 1 and 0. The correlating broken lines based on Goldschmidt's scale intersect the level of unity at  $1.195 \sim 1.23$  ( $= 1/0.84 \sim 1/0.81$ )  $\text{\AA}^{-1}$ . It seems noteworthy that the ionic radius,  $0.81 \sim 0.84$   $\text{\AA}$ , corresponding to the concerned intersection, is almost equal to the ionic radius of magnesium or ferrous iron. (According to Goldschmidt<sup>8</sup>, the ionic radii of magnesium and iron (II) are  $0.78$  and  $0.83$   $\text{\AA}$ , respectively.) The fact that the partition coefficient for a hypothetical lanthanide with the ionic radius similar to magnesium or ferrous iron is presumed to be 1 can be regarded as very reasonable, inasmuch as the species of leading metallic cations in ultrabasic and basic rocks are magnesium and ferrous iron.

On the other hand, the broken lines in Fig. 1 intersect the level of partition coefficient 0 at  $0.73 \sim 0.765$  ( $1/1.37 \sim 1/1.31$ )  $\text{\AA}^{-1}$ . Although it is difficult to present a unique interpretation of this result on limiting size of ionic radius, it is of interest to note that the ionic radius of oxygen anion usually adopted ranges from  $1.32$  to  $1.40$   $\text{\AA}$  (ref. 9). It may be justifiable to infer that the cation having the ionic radius larger than that of oxygen anion is prohibited

from finding its primary way into the closely packed structure of solid oxide. (This interpretation was applied to the estimation of partition coefficients of lanthanides<sup>10</sup> for calcium-controlled process.)

The extension and general application of these findings to other elements form a very interesting problem. Actually, such an investigation<sup>6</sup> was made on the basis of crustal abundances presented by Ahrens and Taylor<sup>11</sup>, and of chondritic abundances of elements. Although the

Fig. 1. Correlation between partition coefficients of lanthanides and reciprocals of their ionic radii<sup>6</sup>. Open circles are based on ionic radii by Goldschmidt<sup>8</sup>, while solid circles on ionic radii are from Templeton and Dauben<sup>7</sup>.

sequence of such an investigation appeared to conform to the regularity expected from lanthanides, some uncertainty remained, for it is doubtful whether Ahrens-Taylor's abundances are representative of crustal abundances of elements and whether they correspond to the same liquid fraction value.

Therefore, it is desirable to direct attention to the average abundances for basic rocks, though it is also more or less uncertain whether they correspond to the same liquid fraction value. However, the basic rocks are preferable in that most of them can be considered as liquid-type material and their genetic nature and chemical composition are very simple compared with acidic rocks. For this reason, I dealt with the average abundances for basic rocks<sup>12</sup>. Since the liquid fraction value for average basic rock<sup>3</sup> has been estimated to be about 1/80, it is possible to evaluate the partition coefficient<sup>6</sup> from the average abundance for basic rocks, if the relevant abundance for initial material is known. For some elements such as lanthanides<sup>4,5</sup>, uranium and thorium<sup>3</sup>, it was shown that the chondritic abundances can be regarded as representing the initial concentrations for the Earth. As regards alkali metals, however, it has been questioned<sup>13</sup> whether their chondritic abundances can represent their abundances in the original oxide material of the Earth. In fact, if the partition coefficients of alkali metals are calculated, taking their chondritic abundance to be representative of the Earth's initial abundance of alkali metals, values much smaller than expected are obtained. Consequently, so long as reference is made to chondrites, it appears to be impossible to extend the limiting effect by oxygen anion to alkali metals.

Fig. 2. Dependence of partition coefficient on the reciprocal of the ionic radius and on valency. Partition coefficients for rubidium and strontium are from ref. 1, that for lead from ref. 2, those for thorium and uranium from ref. 3, and those for lanthanides from refs. 4 and 5; for open circles, see text. (Correlating lines may not converge but tend to run in parallel. However, it makes a slight difference to the size limit, because the partition coefficients have been obtained for large ions)

Meanwhile, I have succeeded<sup>1</sup> recently in evaluating the partition coefficient of rubidium exclusively from the abundance variation in terrestrial materials (basic rocks) without any reliance on meteorites. As a result, it has been shown that the value for the abundance of rubidium in chondrite cannot be used as an initial rubidium abundance which is pertinent to the genesis of our basic rocks. Moreover, in contrast to the result of preliminary inspection based on the chondritic data, it has been also indicated that the partition coefficient of rubidium is not aberrant but regular in relation to the bearing on ionic radius.

The resulting partition coefficients have been plotted in Fig. 2 together with those for other elements. (In this diagram, the partition coefficients derived from, or endorsed by, terrestrial abundance variations are shown in solid circles, while those calculated merely from a comparison<sup>6</sup> of the average basic rock with the chondrite are expressed by open circles.) As to bivalent elements, it is a debatable problem whether the major elements magnesium and calcium can be treated in the same way as many of the minor elements. Nevertheless, it has been shown<sup>12</sup> that the major bivalent elements can in general be treated in the same way as minor bivalent elements. In any case, it may be necessary to deal separately with a group of bivalent elements, probably inclusive of minor elements, for the leading metallic cations in ultrabasic or basic rocks belong to this group.

Fig. 3. Dependence of size limit for partition on valency (cf. Fig. 2)

The limiting value of ionic radius corresponding to partition coefficient 0 (cf. Fig. 2) is shown as a function of valency in Fig. 3. (As to the partition coefficient of a univalent element, there is only one value, that is, that for rubidium. Accordingly there exists some uncertainty about the size limit for univalent series, but the value shown in Fig. 3 could be regarded as fairly reliable.) It is seen that the size limits for partition are comparable with that of the oxygen anion. In addition, it seems to be significant that the size limit for partition of elements with increasingly larger electric positive charge becomes smaller. As a possibility, this can be interpreted as suggesting that the oxygen anion behaves as a smaller sphere towards the cation with higher electric charge. (It should be noted that Pauling<sup>14</sup> gave the value of 1.76 Å to oxygen for a univalent crystal and 1.40 Å to oxygen for a polyvalent crystal.) That is, Fig. 3 can be interpreted as reflecting the coulomb effect. However, the possibility cannot be ruled out that compressibility may be connected to a lesser extent with this phenomenon.

## DISTRIBUTION PATTERN OF AMYLASE ACTIVITY IN SERUM PROTEINS

By DR. M. ATAUR RAHMAN

Department of Biochemistry, Jinnah Post Graduate Medical Centre, Karachi (Pakistan)

**A**MYLASE activity of serum has been reported by several workers to be associated either with albumin or with globulin or with both. McGeachin and Lewis<sup>1</sup> reported that in normal human serum amylase activity was chiefly associated with the albumin fraction of a serum, a conclusion based on electrophoretic investigations. McGeachin and Potter<sup>2</sup> have suggested that this was not the case for rat serum, and the largest fraction of the serum amylase recovered from the electrophoretic pattern was associated with  $\beta$ -globulin and a lesser amount with  $\gamma$ -globulin. It was further suggested that the distribution pattern of serum amylase may vary in different species.

The amount of serum amylase activity varies widely in different species and the activity is not related to the carbohydrate content of the normal diet of a particular species. For example, rabbits have a lower serum amylase content than dogs. Evidence is presented here that the distribution pattern of amylase activity in the serum proteins of man, dog, rat and guinea-pig is the same and that amylase activity is associated with the globulin fraction.

The blood samples from guinea-pigs and rats were withdrawn directly from the heart under mild ether anaesthesia. The samples from men and dogs were obtained by vein-puncture. Serum was obtained from fresh blood samples and the serum proteins were fractionated by the method of Reinhold<sup>3</sup>, where the precipitation of globulin is effected by a solution of a mixture of sodium sulphate and sodium sulphite (27.8 per cent). This method was originally recommended for routine estimation of albumin and globulin fractions.

Serum and sulphate-sulphite solution were mixed in the ratio of 1:15 in a centrifuge tube; 7.5 ml. of ether per ml. serum was added and shaken. Usually 2 ml. of serum was taken in each case. It was centrifuged just long enough for a firm globulin layer to form. The clear solution below the globulin layer was carefully removed quantitatively and contained all the albumin fraction. The globulin precipitate was washed twice with sulphate-sulphite mixture and the washings were added to the albumin fraction. The globulin precipitate was dissolved in saline after removal of ether. The albumin and globulin fractions were dialysed separately against running saline at 4° C for 36–48 h to remove all the sodium sulphate and sodium sulphite. The whole serum was also similarly dialysed. The contents of the dialysing bags were then adjusted to a known volume with saline and amylase activity was measured.

Serum amylase activity was determined in terms of the amount of reducing sugar formed when serum was incubated with starch at 38° C. The amount of the solution equivalent to 0.05 to 0.1 ml. of the original serum was added to a buffered starch substrate (0.1 per cent starch in saline with 12.5 mM potassium phosphate buffer, pH 6.9) containing 1 mg of soluble starch (Fisher Scientific Co.), and incubated for 15 or 30 min. A control was similarly prepared without starch. At the end of the incubation period, enzyme activity was stopped by addition of 1 ml. of 0.1 N sodium hydroxide and 5 ml. of 0.45 per cent zinc sulphate solution. The solutions were kept in boiling water for 4 min and filtered through a cotton plug. The precipitate was washed with two 3-ml.

Table 1. SERUM AMYLASE ACTIVITY

Amylase activity is expressed in terms of mg of glucose equivalent released by 100 ml. of serum in 30 min. Numbers in parentheses represent the number of samples tested in each species

	Whole serum	Amylase units per 100 ml. of serum Dialysed serum	Albumin fraction	Globulin fraction	Total
Man (5)	50	38	2	41	43
Guinea-pig (8)	421	417	4	364	368
Rat (4)	637	618	8	547	555
Dog (6)	793	759	14	729	743

portions of hot water. The reducing sugar was estimated in the filtrate by Hagedorn and Jensen's method.

The difference between test and control values provides a measurement of the amylase activity which was calculated as mg of glucose equivalent released by 100 ml. of serum in 30 min. Two blank experiments were simultaneously run on each day of estimation. The first blank was used to determine the reducing power of 1 mg starch and the value was subtracted from the test values. Another blank was carried out without starch and the value was subtracted from all control experiments.

After dialysis, some of the samples of the serum protein fractions were electrophoresed on paper in barbitol buffer at pH 8.6 and ionic strength of 0.05. The amount of solution of albumin or globulin equivalent to 0.02 ml. of the original serum was subjected to electrophoresis for 16–18 h, along with the samples of dialysed and undialysed serum. The strips were dyed and scanned in the usual way.

The mean values found for human and for guinea-pig, rat and dog sera are summarized in Table 1. The results show that amylase activity was always associated with the globulin fraction of the serum proteins and that activity was slightly less on dialysis.

Fig. 1, which denotes one of the typical electrophoretic patterns of the human serum protein fractions and those

Fig. 1. Electrophoretic pattern of human serum: a, whole serum; b, dialysed serum; c, albumin fraction; d, globulin fraction

and undialysed serum, indicates that the fraction was free from globulin and vice versa, though further separation of the different fractions of globulins was not clear, probably due to dilution and ageing of the serum samples.

These results suggest that enzyme activity is always associated with globulin fraction and does not differ from one species to another, at least among the species tested. The results are therefore not in agreement with those of McGeachin and his co-workers<sup>1,2</sup>, but they do agree with those of Baker and Pellegrino<sup>4</sup>, who showed that amylase activity was principally in the globulin fraction. Both groups of workers have based their separation of the fractions on electrophoresis. It has been pointed out that the measurement of paper electrophoresis is uncertain because of protein-protein and protein-paper indications<sup>3</sup>.

These observations, apart from showing that enzyme activity is always associated with the globulin fraction, also indicate that the separation of the fractions of the serum proteins by the Reinhold method is complete.

McGeachin and Lewis<sup>1</sup> indicated the presence of an inhibitor of amylase in human serum which was undialysable; they found that the sum of the amylase activities of the electrophoretically separated fractions of normal serum was greater than the amylase activity of the whole serum. In this investigation the presence of inhibitor was not indicated at all when the serum proteins were fractionated into albumin and globulin fractions. The total amylase activity of the two fractions was, however, slightly lower than the amylase activity of the whole serum, dialysed or undialysed, except in the case of human serum, when the total activity of the albumin and globulin fractions (Table 1) was higher than that of the activity of dialysed serum. This suggests that if a protein inhibitor is present, then this protein is associated with the globulin fraction, as nearly all the amylase activity is associated with this fraction.

## RUMEN MICROBIAL POLYNUCLEOTIDE SYNTHESIS AND ITS POSSIBLE ROLE IN RUMINANT NITROGEN UTILIZATION

By PROF. W. C. ELLIS\* and PROF. W. H. PFANDER

Department of Animal Husbandry, University of Missouri, Columbia

IT now appears that a major proportion of the nitrogen absorbed from the ruminant's digestive tract is represented by molecular combinations arising from the metabolic action of rumen micro-organisms on dietary forms of nitrogen. The principal products of this microbial metabolism are ammonia and amino-acids derived from the subsequent intestinal digestion of rumen microbial protein. This report presents evidence that microbial polynucleotide nitrogen represents an appreciable proportion of rumen microbial nitrogen and suggests that the conversion of dietary nitrogen to polynucleotides, and their subsequent digestion and metabolism, may explain several phenomena related to ruminant nitrogen utilization.

Rumen-cannulated sheep were fed diets essentially devoid of ribonucleic (RNA) and deoxyribonucleic (DNA) acids and protein (by the analytical methods employed) and supplemented at a level of 10 per cent with one of the nitrogen sources listed in Table 1. These sources were employed because, due to their solubility in 70–80 per cent ethanol, they could be separated from microbial protein and nucleic acids. Samples of rumen ingesta were obtained shortly after the morning feed, and placed in 39° C anaerobic incubation tubes. 10 ml. sub-samples were removed immediately and at intervals up to 12 h. Methods of analysis were based on a modification<sup>1</sup> of the Schmidt and Thannhauser<sup>2</sup> procedure by which RNA and DNA phosphorus were determined. RNA and DNA nitrogen values were calculated assuming a phosphorus to nitrogen ratio of 8:15.3 (ref. 3).

Microbial nitrogen per 10 ml. ingesta increased with incubation time during all experiments, as indicated by the ranges recorded in Table 1, and was highly significantly, positively correlated with RNA ( $r = 0.72$ ) and total polynucleotide ( $r = 0.80$ ) nitrogen. Therefore, for brevity, the nitrogen contribution of these polynucleotides is expressed in Table 1 as a mean percentage of microbial nitrogen. RNA-N comprised from 10.4 to 14.8; DNA-N, 2.2–4.1, and total polynucleotide nitrogen, 13.8–18.4 per cent of the microbial nitrogen.

An indication of the magnitude of conversion of dietary nitrogen to microbial nitrogen and polynucleotide nitrogen can be obtained from the proportion of the total ingesta nitrogen represented by each. Since each represented an increasing proportion of the total ingesta nitrogen with increasing incubation time, the range and mean of microbial nitrogen and polynucleotide nitrogen expressed as a percentage of total ingesta nitrogen is presented in Table 1. Microbial nitrogen represented 41.1–51.6 per cent of the total ingesta nitrogen in Exp. C involving zein-values which agree well with the *in vivo* conversion of zein nitrogen to microbial nitrogen (at least 40 per cent) reported by McDonald<sup>4</sup>. Microbial nitrogen represented a similar proportion of the total ingesta nitrogen in Exp. G and H to that reported for the *in vivo* conversion of wheat hay nitrogen to microbial nitrogen (62–82 per cent<sup>5</sup>).

Microbial polynucleotide nitrogen represented from 5.0 to 7.6 per cent of the ingesta nitrogen from the sheep fed zein and 8.4–13.3 per cent of the ingesta nitrogen from sheep fed urea and amino-acids. A private communication from Dr. I. W. McDonald indicated that (based on analysis for adenine and guanine and assuming that adenine and guanine represented two-thirds of the total nucleic acid nitrogen) nucleic acid nitrogen represented over 10 per cent of the microbial nitrogen leaving the rumen of sheep fed casein<sup>6</sup>. The *in vitro* data presented here for Exps. G and H agree well with McDonald's *in vivo* results. The lower value for zein, as compared with urea and amino-acids, is consistent with the demonstrated resistance of zein to intra-ruminal degradation<sup>4</sup>. These data suggest that a significant proportion (from 5.0 to 13.3 per cent) of the ruminant's dietary nitrogen is converted to rumen microbial polynucleotide nitrogen and, since microbial nucleosidal and nucleotidal nitrogen was not determined, possibly a larger proportion is converted to microbial purine and pyrimidine nitrogen. This is consistent with an extensive conversion of dietary nitrogen to rumen microbial nitrogen and the relatively large concentration of nucleic acids in various species of bacteria<sup>7</sup>. It also serves to explain several reported observations concerning ruminant nitrogen utilization and excretion.

Blaxter<sup>8</sup> has summarized data indicating that ruminants, as compared with monogastric animals of similar body-weight, excrete a greater (three- to six-fold) daily quantity of purine nitrogen. Whereas daily purine excretion remains essentially constant for the fed and fasted monogastric<sup>9</sup> and suckling calf<sup>10</sup>, it decreases by approximately 50 per cent in the mature ruminant<sup>11</sup> on fasting—thereby indicating an exogenous source of purine excretion by the fed ruminant at least equal to that of endogenous origin. Blaxter and Martin<sup>12</sup> reported experiments in which the intraruminal infusion of casein, free of purine and pyrimidine bases, increased allantoin and hippuric acid excretion when compared with abomasal infusion of identical quantities of casein. These observations are consistent with an extensive conversion of dietary nitrogen to rumen microbial polynucleotides and their subsequent digestion in and absorption from the small intestines, thereby providing a large exogenous source of innutritious purines which are excreted.

Such an intra-ruminal conversion of dietary nitrogen to innutritious purine nitrogen may also partially explain the more efficient utilization of the readily degraded casein for nitrogen balance<sup>13</sup> and weight gains when it is either heat-treated to resist microbial degradation or administered into the alimentary canal posterior to the rumen. Several investigators have determined the biological value (biological value as conventionally used here represents the proportion of nitrogen absorbed from the digestive tract which is utilized for maintenance and growth purposes, that is, retained) of rumen microbial preparations when fed to monogastric animals and found it to be quite high (80 (ref. 14)). Considering the appreciable content of unnutritious purine nitrogen likely to have been present in such microbial preparations, it appears that the biological value of rumen microbial true protein must have been considerably higher than that of total microbial nitrogen. Such a diluting effect by unnutritious purine nitrogen formed from dietary nitrogen offers an explanation for the lower biological value of such proteins as whole egg when fed to the ruminant. Whole egg protein has a biological value close to 100 when fed to growing rats. Several investigators<sup>15,16</sup> have

determined the biological value of whole egg protein to be 80-86.7 for the growing lamb.

There is little doubt that the extensive protein anabolic potential of rumen micro-organisms is indeed a beneficial process to the ruminant's net nitrogen utilization under its usual dietary regime. Such anabolic capabilities permit the ruminant to utilize a wide variety of dietary nitrogenous compounds with an efficiency which varies within a relatively small range<sup>15-17</sup>. It also permits a "protein regeneration cycle"<sup>18</sup> for blood urea<sup>18</sup> and ammonia resorbed into the rumen. It has been the intent of the foregoing discussion to point out that part of the cost of this beneficial rumen microbial protein anabolism is a concurrent conversion of potentially nutritious dietary nitrogen to rumen microbial purine nitrogen which, on subsequent digestion and absorption, is innutritious to the ruminant's tissues and is the origin of the comparatively higher purine excretion of ruminants as compared with monogastric animals.

## STOCHASTIC CONCEPTS IN CLINICAL RED CELL SURVIVAL STUDIES

By DR. PER-ERIK E. BERGNER\*

Karolinska Institutet, Stockholm, Sweden

**R**ADIOACTIVELY labelled red blood cells have to-day become an important tool in the investigation of cell survival in circulating blood. Two basically different methods of labelling can be recognized: (1)

labelling of circulating red blood cells; (2) labelling of red blood cell precursors. The following is essentially confined to (1).

For labelling according to (1),  $^{51}\text{CrO}_4^{3-}$  and  $\text{DF}^{32}\text{P}$  (di-isopropylfluorophosphonate) are to-day the most frequently used substances. The data one generally gets

\* Visiting scientist, Medical Division, Oak Ridge Institute of Nuclear Studies, Oak Ridge, Tennessee.

from such experiments consist of the number of labelled circulating red blood cells as a function of time, that is, the survival curve. However, while much work is frequently devoted to the experimental technique, the theoretical analysis of the data is comparatively confined and primitive. Commonly the only form of 'calculation' performed consists of the determination of the 'half-life'. This parameter, usually denoted by  $t_1$ , has hitherto not been given any generally physico-biological significance and its commonly accepted clinical significance is merely phenomenological and is due to the parameter having been presented together with clinical data for such a long time.

In the literature, the half-life is often calculated from semilogarithmic plots of survival curves; this gives the impression that the parameter originates from an analogy with certain physicochemical processes, for example, radioactive decay. This analogy is misleading and the use of the term 't-fifty' (with the corresponding notation  $t_{50}$ ) would perhaps prevent some confusion and would also be consistent with the unquestionable significance of the parameter: the time after which 50 per cent of the members of the population originally present have died (cf.  $LD_{50}$ ). But the physico-biological significance of the 'half-life' is, of course, still obscure.

In this respect the concept of 'life span' is preferable: knowledge of the life-span distribution over the population of circulating red blood cells would doubtless give some insight into what could be called the 'physiological state' of the system considered. A number of papers discuss cell survival curves on the basis of such a concept<sup>1-3</sup> (for further references, see the review by Berlin *et al.*<sup>4</sup>), but, as explicitly stated by Dornhorst<sup>3</sup>, it is almost impossible to determine the life-span distribution from a survival curve alone. Some knowledge in addition to the survival curve is thus necessary and, since this knowledge must be physiological in character, the question arises whether the conception of life-span has a physico-biological significance that will provide an efficient basis for intuitive reasoning in physiological terms.

From this point of view the 'death probability of a cell' is a more satisfactory concept: considered as a function of the cell age, it is more directly connected with the destruction mechanism than is the life-span distribution. Now, as shown elsewhere<sup>5</sup>, what has commonly been assumed *ad hoc* about the life-span (for example, that it shows a Gaussian distribution) is not consistent with what intuitively seems natural when the death-probability function is considered. So far, the theoretical work indicates that the interpretation of survival data should be performed on the basis of the death-probability function rather than of the life-span distribution. The final choice between the two entities, however, depends to a certain extent on which one is most easily calculated from the results available.

As already stated, the life-span distribution cannot be determined from the survival curve only, and the same is true also for the death probability as a function of the age of the cell. However, a knowledge of the mean value of the corresponding variables even without the complete distribution should be valuable, and in a note published in 1946, Mills<sup>6</sup> has claimed that 'mean life-span' can, in fact, be determined from the initial slope of the survival curve: a statement which implicitly follows from the works by Callender *et al.*<sup>1</sup> and Dornhorst<sup>3</sup>. These authors, however, all include the general assumption of steady-state, and under that assumption the mean life-span is just the inverse of the 'mean death probability'<sup>5</sup>; consequently, under steady-state conditions, the two mean values are equally easy to determine.

But to assume steady state puts a strong restriction on to the system, and the assumption can scarcely be realistic in clinical work. The question then is whether the initial slope of a survival curve has the same significance also under non-steady-state conditions, and, as recent work

has shown (Bergner, in preparation), a definite answer does exist: if the cells are irreversibly labelled independently of their age, the initial slope of a survival curve always determines the mean death probability (the value that this parameter has at the time when the cells are labelled). Or, in more technical terms, if the labelling is proper (according to the preceding sentence) and the number of labelled cells is plotted against time, the initial slope of the curve, when divided by the initial number of labelled cells, is equal to the mean death probability at the time of labelling, independently of whether or not the system is stationary.

In the light of this recent result, let us consider the following equation, derived by Uhlhorn (unpublished work), which gives the general relation between the mean life-span and the mean death probability:

$$\bar{l}(t) = \frac{1}{P(t)} \left( 1 - \frac{d[n(t)\bar{a}(t)]/dt}{n(t)} \right)$$

where  $\bar{l}(t)$  is the mean life-span at the time  $t$ ,  $P(t)$  the mean death probability at the time  $t$ ,  $n(t)$  the total number of circulating red blood cells at the time  $t$ , and  $\bar{a}(t)$  the mean age at the time  $t$  of the circulating red blood cells. In this equation the time derivative becomes different from zero when the system is not stationary, and the relationship might then not only be complicated but also quite undetermined; at present it does not seem possible to determine the derivative experimentally. Consequently, the equation indicates that, under non-steady-state conditions, the mean life-span is not so easily calculated by existing theoretical tools as is the mean death probability, the latter being determinable under quite general conditions.

The theoretical analysis thus supports the suggestion by Garby<sup>7</sup> that the initial slope is a fundamental parameter in clinical practice, not only for theoretical reasons but also as a consequence of the simple fact that in clinical work short-term investigations are preferable to long-term ones. However, many difficulties are associated with initial slope measurements. At present DFP appears to be the only labelling substance that might satisfy the basic requirements, but still more investigations must be carried out to evaluate the details of the labelling mechanism in normal and non-normal systems. Moreover, certain mathematical difficulties are associated with the estimation of initial slopes in general; some of those problems have been investigated in other contexts<sup>8</sup> and the results there might also be applicable here.

By making use of the idea that the red blood cells possess a definite death probability, which is a function of the age of the cell only, it has thus been possible to ascribe a general and, as it seems, practically useful significance to the initial slope of cell survival curves. For a more detailed interpretation of survival curves, however, the form of this death-probability function must be known to a certain extent; this is made necessary by the foregoing fact that the death-probability function cannot be estimated from the survival curve alone. Some knowledge about the death-probability function does already exist, mainly on the basis of precursor labelling (for example, <sup>14</sup>C-glycine)<sup>4</sup>, but more information is needed, especially about certain disease states. Cohort methods, according to the principles recently introduced by Cline *et al.*<sup>9</sup>, might prove useful here.

But, in order to make possible an efficient use of old and new experimental techniques and data, a more sophisticated approach is necessary rather than that creating such a relatively primitive concept as  $t_1$ . The degree of sophistication necessary might be illustrated as follows. Distinction has here been made between the life-span distribution function and the death-probability function; the former gives the probability that a newborn cell will die at a certain age, while the latter, referring

to a randomly chosen cell, gives the probability that the cell will die within the time unit, under the condition of the cell's age. The distinction is evident and significant to those who are familiar with stochastic methodology, but it might be difficult for others to grasp. However, the distinction is fundamental physiologically, showing that the death probability is a more basic concept than is the life-span distribution. To mention but two motives for the last statement: in a non-stationary system the life-span distribution can only occasionally be determined even when the destruction mechanism is known, whereas this very mechanism immediately defines the death-probability function, which also can be directly observed by cohort methods. The second motive has a more direct clinical significance: together with an estimate of the

total number of circulating cells, the mean death probability always determines the total destruction rate (the total number of cells dying per unit of time) while this rate can be determined from the mean life-span only when the system is stationary.

## REVERSIBLE CHANGES IN SHAPE OF RED CELLS IN ELECTRICAL FIELDS

By DR. R. P. RAND, PROF. A. C. BURTON and P. CANHAM

Department of Biophysics, The University of Western Ontario, London, Canada

IN the course of our investigations on the mechanical properties of the membrane of the human red cell by use of the micromanipulator on single cells<sup>1-3</sup>, we inserted polarizable stainless-steel microelectrodes into a hanging drop of isotonic saline containing the cells. When a voltage difference of approximately 2 V or less was applied to the electrodes, some remarkable shape-changes were seen that were completely reversible. Before, the cells were of the normal biconcave disk shape, but when the voltage was applied shape-changes occurred near the anode which were completely different from those near the cathode. Higher voltages lead to the liberation of gas near the electrodes which disturbed the field optically.

Those cells that were near the cathode assumed the shape of crenated spheres (Fig. 1), while those near the anode remained smooth in outline but cup-shaped when seen edge on, with a region of high optical density (a 'refractile body') in the 'dimple' region. The transformation took only a few seconds in the case of those cells which were close to the electrodes, and longer for those farther away. Reversal of the voltage gradient reversed the transformation of individual cells. For lower voltages, the time required for the transformation was greater. On removal of the voltage gradient the cells return to their normal biconcave shape. The crenated and cup-shaped cells could be seen clearly in the area of current flow, while cells outside this showed very little or no change. Some cells, usually those showing micro-crenation, did not change on reversing the current. Fig. 2 shows a magnified picture of a group of cells between the electrodes, in which the changes in individual cells could be seen when the polarity of that electrode was reversed.

One observation made in these experiments seemed to us to be of importance. If a single cell undergoing crenation was observed, the emergence of a particular 'bump' or 'pimple' of crenation could be seen, which disappeared when the voltage was removed; this occurred repeatedly at the same place on the membrane of that cell. Furchgott<sup>4</sup> and Ponder<sup>5</sup> also made this observation. This would strongly suggest that crenation does not represent a random sort of folding of the membrane, but

Fig. 1. Shape changes in red cells close to the same electrode when it changes from cathode (A) to anode (B). The voltage difference was about 2 V. The scale indicates 10  $\mu$ . With no voltage, most of the cells in the field returned to normal biconcave shape.

Fig. 2. The field between the two electrodes, showing changes in individual cells when the polarity was reversed. Cells outside the main potency of the current, or in the centre of the field, change very little.

Fig. 3. Demonstrating the violent change in pH occurring between the electrodes when the voltage is applied. This, rather than electrical forces, may be the primary factor

that a definite mosaic of discontinuities exists over the membrane of the normal cell.

It is not at all likely that the effects are primarily due to the electrostatic field. There is a considerable density of current which produces a marked local change of pH, with a very high pH near the cathode, and a very low pH near the anode. This was demonstrated by adding a mixture of two indicators, bromthymol blue and phenocresol purple (yellow below pH 6, purple above pH 8), to the hanging drop. The areas of pH change could easily be observed by the colour changes, but were less easily photographed (Fig. 3). Changes of pH produced without any applied electrical field also lead to crenation at high pH, and smooth cup-shaped cells at low pH. This was demonstrated by spraying the cells with isotonic saline which had been made very alkaline with sodium hydroxide, or made very acid with hydrochloric acid. These changes in shape were also demonstrated by Furchgott<sup>4</sup>, but little was made of the fact that the shape changes were completely different at the 'two' levels of pH. In the case of the low pH the unique region of concavity (dimple) was preserved (as the cup region), but at the high pH the dimple region was lost and the crenated cells were spherically symmetrical.

It was questionable whether the presence of the normal concentrations of haemoglobin was required for this phenomenon. In order to answer this, we investigated the phenomenon in red cell ghosts. Since phase-contrast microscopy is required in this case, we have not yet succeeded in carrying out the experiments with electrical

fields, and an apparatus will have to be specially designed to avoid optical disturbance. However, the changes in high and low pH (which are apparently identical with those in the electrical field for normal cells) have been investigated in ghosts. Ghost cells became extremely thin at high pH rather than crenated like normal cells. At low pH, ghost cells showed no changes comparable with those of normal cells (they are not cup-shaped, with region of high optical density). We concluded that the cup-shape phenomenon is dependent on the presence of haemoglobin, and that crenation is considerably modified in the absence of high concentration of haemoglobin.

Whatever the mechanism and interpretation of this phenomenon, the use of the electrodes provides a convenient way of producing perfectly reversible changes in the shape of the red cell. Such an investigation may help to elucidate the difficult problem of forces responsible for the normal biconcave shape of the red cell. Biophysical analysis of this has led us to search for an external force, such as a mutual attraction between the membranes in the dimple region.

From these and other observations of the process of crenation, we are forced to accept the view that the membrane of the red cell cannot be uniform in its own plane, but has a mosaic pattern of charges, or of active groups, fairly regularly spaced over the surface, at intervals of 0.5–1.0  $\mu$ . Possibly the forces of interaction between these centres of charge may underlie the force of attraction between the membranes, which we suggest is responsible for the biconcave shape and for the positive hydrostatic pressure within the cell<sup>1</sup>. The same reasoning may hold for the obvious attraction of the membrane of one red cell for that of another which shows itself in the tendency to form rouleaux. Experiments with red cells treated with the enzyme neuraminidase, which removes the surface charges, are being pursued to supply further evidence on this view.

The work was supported by a grant from the Life Insurance Medical Research Fund.

## BIOCHEMICAL DEFECT CAUSING CONGENITAL GOITRE IN SHEEP

By DR. I. R. FALCONER\*

Department of Agricultural Biochemistry, Waite Agricultural Research Institute, University of Adelaide

**C**ONGENITAL goitre in man, which is associated with defects in the biosynthesis of thyroid hormone, has recently aroused much interest, and a number of these cases have been described<sup>1</sup>. In three of the congenital disorders a definite biochemical lesion has been demonstrated in the goitrous gland<sup>2-4</sup>, but the other categories of congenital defects are heterogeneous groups.

The recent widespread occurrence of goitre in South Australian Merino lambs born in areas with no previous history of thyroid abnormality has led to an investigation of the underlying causes. The data presented in this article are restricted to a biochemical investigation of the goitre

tissue, and do not deal with results for the parallel work on field occurrence, pathology and genetic origin of the goitre.

The goitres were obtained from 1–3-year-old Merino rams and ewes. The sheep were held in partially roofed pens and fed on hay chaff and oats. Goitrous tissue excised under aseptic surgical conditions was immediately sliced into strips and chilled in ice. The goitres varied in weight from 13 g to more than 100 g for the two lobes. The general appearance of the goitre on surgical exposure was of a firm elastic structure of deep red colour with an extremely good blood supply. In some cases the lobes were fused into a single mass, but in the majority the two lobes were of normal location and shape. Normal sheep thyroid glands were obtained immediately after

\* Present address: Department of Agricultural Sciences, University of Nottingham School of Agriculture, Sutton Bonington, Loughborough, Leics.

slaughter at the abattoirs, and placed in ice. Until it was required for analysis the thyroid tissue was stored at  $-15^{\circ}\text{C}$ .

The iodinated amino-acid content of normal and goitrous thyroid tissue was determined after enzymatic hydrolysis of homogenates, followed by ion exchange column separation of amino-acids<sup>6</sup>. The column eluate was bulked and evaporated to dryness in a rotary film evaporator, and the solid residue re-dissolved in 2 N ammonium hydroxide 1 part: ethanol 3 parts. Portions of the re-dissolved amino-acid extract were chromatographed on Whatman No. 1 paper using a solvent of butanol 2 parts: 2 N ammonium hydroxide 1 part: ethanol 1 part. The chromatograms were cut up and the iodinated amino-acid content determined<sup>6</sup>. The results of this analysis are shown in Table 1.

Table 1. IODINATED AMINO-ACIDS LIBERATED BY ENZYMATIC HYDROLYSIS FROM HOMOGENATES OF GOITROUS AND NORMAL THYROID GLANDS OF SHEEP ( $\mu\text{g/g}$  FRESH WT)

Sample	Moniodotyrosine	Diiodotyrosine	Thyroxine
Normal	60	215	58
Goitre Y87	15.1	23.2	0.4
Goitre Y135	2.8	23.7	2.5
Goitre Y190		7.1	0.2
Goitre WL133	9.7	10.0	0.0
Goitre L1	5.8	32.9	2.0

\* Total moniodotyrosine and diiodotyrosine.

Although the iodinated amino-acid content of the goitrous thyroids varies considerably, it is clear that they contain about one-tenth that of the normal. Diiodotyrosine was in the largest proportion, as in the normal gland.

The protein patterns of normal and abnormal thyroid tissue were examined<sup>7</sup> in a double sector cell run on a Spinco model E analytical centrifuge, and the mobility of the protein components measured. Extracts of the goitrous thyroids gave a characteristic ultracentrifuge pattern (Fig. 1a), with one peak of  $S_{20w}$  3.2–7.6, and a very small peak of  $S_{20w}$  50.4 and 55.9 in two out of 12 glands. Normal thyroid extracts showed three consistent peaks in the ultracentrifuge (Fig. 1b) at  $S_{20w}$  3.3–5.0,  $S_{20w}$  18.5–19.1 and  $S_{20w}$  27.6–27.9. The thyroglobulin peak at  $S_{20w}$  18.5–19.1 in the normal thyroid extract contains 72.7 per cent of the total protein, as measured from the peak area corrected for radial dilution. It is clear that there is no detectable thyroglobulin in the goitrous glands of untreated sheep.

The effects of thyroxine therapy on the accumulation of thyroglobulin in the goitres was investigated in three sheep injected intramuscularly with 0.1, 1.0 and 2.0 mg of thyroxine daily for 40 days. The two higher doses of thyroxine were approximately three and six times the daily requirement. The protein-bound iodide level of the serum of the animal given 1 mg/day increased from 3.9  $\mu\text{g}/100\text{ ml.}$  to 17.7  $\mu\text{g}/100\text{ ml.}$  in 17 days. Thyroglobulin was not detected in these treated goitres by the ultracentrifuge method (Fig. 1c). It therefore appears likely that the synthesis of thyroglobulin was impaired in these

Fig. 1. Ultracentrifuge patterns obtained from 0.9 per cent sodium chloride extracts of thyroid tissue. a, Goitrous thyroid extract, 0.84 per cent protein; 28 min at 37,000 r.p.m. Spinco E, double-sector cell. b, Normal thyroid extract 0.99 per cent protein; 28 min at 36,960 r.p.m. Spinco E, double-sector cell. c, Goitrous thyroid extract from sheep given 1 mg thyroxine/day for 40 days, 0.96 per cent protein; 29 min at 35,000 r.p.m., Spinco E, double-sector cell.

goitres, rather than rapid proteolysis preventing the appearance of any thyroglobulin.

The synthesis of thyroglobulin in normal and goitrous thyroid glands was examined by following the incorporation of  $^{14}\text{C}$ -proline and  $^{14}\text{C}$ -leucine into thyroid tissue slices. Fresh thyroid tissue chilled in ice was chopped to 0.5 mm slices on a Mickle (Gomshall, Surrey) tissue chopper and 0.2-g portions were quickly transferred to 1-ml. portions of chilled Tyrode's solution (pH 7.4). Duplicate portions contained 20  $\mu\text{g}$  cycloheximide ('Actidione', Upjohn Corp.), which is an inhibitor of protein synthesis<sup>8</sup>. The tissues were incubated with either 0.5  $\mu\text{C}$ . or 0.25  $\mu\text{C}$ .  $^{14}\text{C}$ -proline or  $^{14}\text{C}$ -leucine (Schwarz BioResearch Inc.) 100 mc./mmole. Duplicate portions of normal and goitrous slices were immediately frozen in dry ice-acetone mixture. The remaining portions were incubated at  $37.5^{\circ}\text{C}$  in a water bath for up to 3 h and at the end of incubation the material was frozen and stored at  $-15^{\circ}\text{C}$ .

The incubated slices were thoroughly homogenized with 3 M 'Ballotini' beads using a motor-driven 'Teflon' pestle, while partially frozen. Following the addition of 2-ml. proline solution (1 mg/ml.), cellular debris and larger particles were sedimented at 20,000g in a Spinco model L preparative ultracentrifuge.

The supernatant material was fractionated with ammonium sulphate as shown in the individual experiments. The protein fractions were redissolved in water, and precipitated with trichloroacetic acid at 5 per cent w/v. The resulting precipitate was resuspended in water and centrifuged at 2,000g. The precipitate was resuspended in 1 ml. of water and 0.5 ml. of it was transferred to 10 ml. 'Diotol' liquid scintillator fluid<sup>9</sup>. After thorough dispersion of the protein and 24-h storage at room temperature in the dark, the radioactivity was determined on an Ekco liquid scintillation counter and scaler (models N664A, N610A).

The incorporation of 0.5  $\mu\text{C}$ .  $^{14}\text{C}$ -proline into the protein fraction precipitated by 50 per cent saturated ammonium sulphate is shown in Fig. 2. The incorporation of the tracer (1.8 per cent), which was linear over 3 h in both normal and goitre preparations, was largely inhibited by 'Actidione'.

Fig. 2. Incorporation of  $^{14}\text{C}$ -proline into soluble proteins of normal (●) and goitrous (×) thyroid slices. 0.2 g of 0.5 mm thick slices incubated with 0.5  $\mu\text{C}$ .  $^{14}\text{C}$ -proline at  $37.5^{\circ}\text{C}$  for up to 3 h. Duplicate samples incubated with 20  $\mu\text{g}$  'Actidione' (cycloheximide) (Δ). Radioactivity measured in 50 per cent saturated ammonium sulphate precipitate from 20,000g supernatant of a slice homogenate.

Further experiments were carried out in which 0.25 and 0.5  $\mu\text{C}$ .  $^{14}\text{C}$ -proline and  $^{14}\text{C}$ -leucine were incubated with the thyroid slices. The supernatant material was again fractionated with ammonium sulphate. Precipitates were obtained at 0–35 and 35–45 per cent saturation, and the fraction soluble at 45 per cent saturation retained. All fractions were finally precipitated with trichloroacetic acid to 5 per cent. The results of one of these experiments is shown in Fig. 3.

The incorporation of  $^{14}\text{C}$ -amino-acids into the 35–45 per cent ammonium sulphate fraction, which is largely thyroglobulin, is greatly reduced in the goitrous slices.

Fig. 3. Incorporation of  $^{14}\text{C}$ -leucine into soluble proteins of normal (●) and goitrous (x) thyroid slices. 0.2 g of 0.5 mm thick slices incubated with 0.25  $\mu\text{C}$   $^{14}\text{C}$ -leucine at  $37.5^\circ\text{C}$  for 3 h. Duplicate samples incubated with 20  $\mu\text{g}$  'Actidione' (cycloheximide) (A). Radioactivity measured in 20,000g supernatant fractions of a slice homogenate precipitating at 0-35 per cent saturated ammonium sulphate, 35-45 per cent saturated ammonium sulphate (thyroglobulin fraction) and 45 per cent saturated ammonium sulphate-5 per cent trichloroacetic acid.

This is in marked contrast to the incorporation of  $^{14}\text{C}$ -leucine into the other fractions which is higher in the goitrous than in the normal slices. Thyroxine therapy at 1 mg/day for 40 days to the goitrous animal repressed the incorporation of  $^{14}\text{C}$ -proline to approximately normal levels in the 0-35 per cent ammonium sulphate and 45 per cent ammonium sulphate-5 per cent trichloroacetic acid fractions (Fig. 4).

Recent investigations of thyroglobulin synthesis in pieces of normal thyroid tissue<sup>10</sup> have shown that the  $^{14}\text{C}$ -amino-acids appear in the follicular lumen as thyroglobulin after an incubation period of 4 h. During this time it is suggested that the uniodinated protein is synthesized, four large polypeptide units are aggregated, and the protein passes out of the cell. It is likely, therefore, that the results of 3-h incubation with  $^{14}\text{C}$ -amino-acids, as described here, indicate the rate of intracellular biosynthesis of thyroglobulin, which is relatively unaffected by proteolytic reactions in the follicular lumen.

Fig. 4. Incorporation of  $^{14}\text{C}$ -proline into soluble proteins of normal (●) and goitrous (x) thyroid slices. The goitrous tissue was removed from a rat after 40 days therapy with 1 mg thyroxine/day. 0.2 g of 0.5 mm thick slices incubated with 0.5  $\mu\text{C}$   $^{14}\text{C}$ -proline at  $37.5^\circ\text{C}$  for 3 h. Otherwise as described for Fig. 3.

It is clear that the ultracentrifuge patterns and the results of  $^{14}\text{C}$ -amino-acid incorporation studies described in this article indicate a defect in the biosynthesis of thyroglobulin in the congenital goitre. This primary lesion is in turn responsible for the secondary effects of thyroid enlargement, elevated  $^{131}\text{I}$  uptake, low iodinated amino-acid content of the gland and high level of thyroid-stimulating hormone in the serum.

I thank Mr. C. Mulhearn and the South Australian Department of Agriculture for the experimental animals, and Dr. S. B. Wilson for the ultracentrifuge analysis.

## RECOVERY FROM THE 'LETHAL' EFFECTS OF CROSS-LINKING ALKYLATION

By DR. A. LOVELESS, JUDY COOK and PAMELA WHEATLEY

Institute of Cancer Research, Royal Cancer Hospital, London, S.W.3

IT is well established that the ability of bacteria to survive to produce visible colonies after exposure to ultra-violet or ionizing radiation is markedly dependent on post-irradiation cultural conditions. In particular, incubation under otherwise sub-optimal conditions, as on minimal medium or at low temperatures, generally favours survival though the response may not be the same for different strains<sup>1</sup>. In the case of ultra-violet irradiation it is becoming clear that survival is enhanced in circumstances which permit metabolic repair of otherwise lethal primary lesions, that is the excision and replacement of DNA nucleotides which have suffered dimerization between adjacent thymine moieties<sup>2</sup>. Radiation-sensitive strains may lack the repair equipment.

That a comparable phenomenon may occur after alkylation is indicated by the work of Strauss<sup>3,4</sup> and of Strauss and Wahl<sup>5</sup>, who investigated the consequences of methylation of *Bacillus subtilis* transforming principle by the monofunctional alkylating agent methyl methane sulphonate. It is known from the work of Lawley and Brookes<sup>6</sup> that the most important site of reaction by this agent in DNA is N<sub>7</sub> of guanine with N<sub>3</sub> of adenine coming

a poor second; reaction at other sites is negligible at 'physiological' doses.

Bifunctional alkylating agents such as the di(2-chloro-ethyl) amines and sulphides (nitrogen and sulphur mustards) are enormously more nucleotoxic than their monofunctional analogues and there is now little doubt that this is due to their ability to establish covalent cross-links between the two strands of a duplex DNA<sup>7,8</sup>. The earliest published indication that the survival of bacteria exposed to these agents might also depend on post-treatment cultural conditions is to be found in a report by Harold and Ziporin<sup>9</sup>, who mention in a footnote that survival of *Escherichia coli* was higher on a minimal salts medium than on nutrient agar. (In 1955 Loveless and Miss Stock observed an apparent recovery of both ultra-violet- and nitrogen mustard-treated *E. coli* during overnight storage in phosphate buffer solution. True recovery appeared so unlikely at that time that the phenomenon was attributed to residual division and the work was not reported.) Harold and Ziporin also observed excretion of material absorbing at 260 mμ after mustard gas treatment even when the cells were suspended in

buffer solution. No such excretion occurred, however, from nitrogen mustard-treated cells. Shields<sup>10</sup> found that the survival of nitrogen mustard-treated *E. coli* K-12 may be considerably enhanced by a variety of post-treatment manipulations including the use of minimal media and what would normally be non-optimal incubation temperatures. Haynes (ref. 11 and personal communication) observed that the colony counts afforded by plating *E. coli* exposed *in perpetuo* to nitrogen mustard in phosphate buffer fell to a minimum (corresponding to the exhaustion of the reagent by hydrolysis) and thereafter rose again. This observation was not extended, but Patrick, Haynes and Uretz<sup>12</sup> have reported the recovery of nitrogen mustard-treated yeast during storage in buffer.

We have investigated the phenomenon of recovery in *E. coli* strains *B*, *B/r* and K-12 ( $\lambda$ ) treated with mustard gas (di(2-chloroethyl)sulphide, 'H'). *H* has one great advantage over a nitrogen mustard such as di(2-chloroethyl)methylamine ('HN 2') for such investigations in that it can be assumed to have reacted completely in 20 min at 37° C. The reaction of HN 2 may not be complete in under 3 h under comparable conditions<sup>13</sup> and thus one might search for evidence of recovery while inactivation continues. We also report some experiments concerned with spontaneous recovery of mustard-treated phage T 2 *in vitro*.

Cells in logarithmic phase in broth culture were centrifuged, washed and resuspended in M-9 buffer in stoppered tubes for treatment at 37° C. *H* was added as a 0.1 M solution in dry acetone and the tubes vigorously agitated during and after addition. After 2 min, sodium thiosulphate was added to give 2 per cent w/v and a further 5 min was allowed for the destruction of any available *H*. Controls were run with acetone alone. The treated cells were then diluted extensively ( $> 10^{-3}$ ) into M-9 buffer for storage at 37° C. In initial experiments care was taken that the concentration of dead cells was the same in each storage tube, where necessary by the addition of heat-killed cells, lest these should act as a source of nutrients for survivors. This was found not to be the case and the precaution was afterwards relaxed. Platings were done immediately on nutrient broth (Difco) and on minimal-salts (Davis's<sup>14</sup>) agar and at intervals thereafter up to about 24 h on broth agar. Samples were run over the surface of the agar without use of a contact spreader since the latter has been shown by Shields (personal communication) to result in a considerable reduction in the colony count afforded by cells treated

Fig. 1. Recovery pattern of *H*-treated *E. coli* *B* in phosphate buffer. 1, Control; 2,  $0.5 \times 10^{-4}$  M; 3,  $2.0 \times 10^{-4}$  M; 4,  $5.0 \times 10^{-4}$  M. All treatments for 2 min

Fig. 2. Recovery pattern of *H*-treated *E. coli* *B/r* in phosphate buffer. 1, Control; 2,  $1.5 \times 10^{-4}$  M; 3,  $4.0 \times 10^{-4}$  M; 4,  $6.4 \times 10^{-4}$  M. All treatments for 2 min

Fig. 3. Survival curves for *H*-treated *E. coli* strains *B* and *B/r* plated on nutrient broth and minimal medium. —●—, Strain *B*; lower curve, broth; upper curve, minimal. —○—, Strain *B/r*; lower curve, broth; upper curve, minimal

with alkylating agents. Plates were conveyed to the incubator immediately after spreading since keeping them at low temperature for a time enhanced the survival on broth of both *B* and *B/r*.

Untreated cells of strain *B* proved wholly stable in buffer at 37° C, showing no significant fluctuation in viable count up to 28 h. *H*-treated cells gave steadily rising viable counts which took longer to reach a maximum the more severe the treatment. Untreated *B/r* appeared to be less stable, although the counts were not wholly reliable. As with strain *B*, treated cells showed an appreciable recovery at all doses, but the erratic control prevented any conclusion regarding the positions of the maxima. Figs. 1 and 2 depict the viable counts adjusted only for the plating dilutions.

Fig. 3 presents the survival curves obtained by plating immediately after the thiosulphate 'decontamination' on broth and minimal agar. The vertical arrows indicate the recovery observed on storage in buffer; in the case of strain *B* these all refer to 12-h storage, in the case of *B/r* the maximum observed counts. A third 'recovery point' for *B/r* lies off the figure but it falls very close to the extrapolated curve for survival on minimal medium.

We have performed a few auxiliary experiments, comparable with the foregoing but using the mono-functional sulphur mustard 2-chloroethyl 2'-hydroxyethyl sulphide ('half-*H*'). Unfortunately, at the considerably higher stoichiometric doses that it is necessary

to use with monofunctional compounds to effect a degree of primary inactivation comparable with that achieved with their bifunctional analogues, the lethal effects of spontaneous depurination<sup>15</sup> must become a significant factor during post-treatment storage. Thus, as with *HN 2*, one is seeking evidence of recovery against a background of continuing inactivation but in this case one which persists longer. With a treatment leaving about 5 per cent initial survivors a three-fold increase in the viable count of strain *B* was observed during 6 h. When the initial survival was reduced to 0.1 per cent the subsequent counts remained constant. With *B/r*, which requires higher doses than *B* for equal degrees of inactivation, the counts either remained constant (10 per cent survival) or declined (0.2 per cent survival). This is the sort of result one would expect if recovery were competing with a secondary inactivation effect from which no recovery is possible.

No recovery of *T 2* monocomplexes as plaque-forming units was observed following treatment with *H* to any level of survival. *H* is an extremely good inducing agent of phage  $\lambda$  in *E. coli* strain *K-12* ( $\lambda$ ) (ref. 16). We have treated *K-12* ( $\lambda$ ) at optimal inducing doses and then followed the plaque (induced cell) and colony (viable cell) counts afforded by the treated culture during storage in buffer. The plaque counts fell rapidly, reducing to 1 per cent in 1.5 h. However, after a transient increase (up to four-fold during the first 30 min), the viable counts also fell away. Thus it remains doubtful whether a recovery from the inducing lesion has been observed.

Apart from any considerations of metabolic recovery from the effects of cross-linking alkylation, there is reason to suppose that recovery might occur spontaneously in some circumstances. Phage *T 2* retains infectivity following alkylation by *HN 2* if only one arm of each molecule of the compound is allowed to react with the phage<sup>13</sup>. Brookes and Lawley<sup>17</sup> present results suggesting that *T 2* may also suffer a modicum of base release without loss of infectivity; this suggestion is also implicit in the upward convexity of the survival curves obtained for monofunctionally alkylated *T 2* when plating follows a period of post-treatment incubation<sup>13,18</sup>. Thus a lethal covalent cross-link, established between the two strands of the DNA of a phage particle by *HN 2*, should be able to 'come undone' by base release at one end, leaving the particle only monofunctionally alkylated and carrying an apurinic site. If neither of these conditions is sufficient to inactivate, infectivity should be restored.

We have treated preparations of phage *T 2* with *HN 2* at doses estimated to be equivalent to 1, 2 and 4 phage-lethal 'hits' when sufficient time (3 h) has been allowed for full second-arm reaction (compare ref. 13). After the initial treatment, occupying 2 min, the phage was diluted extensively into *M-9* buffer containing 15 per cent v/v ethanol and a little dissolved gelatine, a medium in which, in other experiments, *T 2* had proved exceptionally stable. Duplicate controls and treatments were run and phage assays carried out at 3 h after treatment, and daily for 3 days thereafter in triplicate. The results are summarized in Table 1, which indicates the proportions of infective centres surviving *HN 2* relative to controls at these times and the mean lethal hit values indicated by these proportions at 3 h (effective end of treatment) and at 19 h ( $\equiv$  maximum of apparent recovery).

Table 1. CHANGES IN INFECTIVE TITRE OF *HN 2*-TREATED PHAGE RELATIVE TO UNTREATED PHAGE DURING POST-TREATMENT STORAGE

Dose (mg/ml/ 2 min)	Mean lethal hits at 3 h	3 h	Infective fraction				Mean lethal hits at 19 h
			19 h	45 h	69 h		
0.1	1	1.3	0.28	0.33	0.34	0.34	1.1
	2	1.2	0.29	0.33	0.31	0.32	1.1
0.2	1	2.2	0.11	0.18	0.12	0.14	1.7
	2	1.9	0.15	0.26	0.14	0.18	1.3
0.4	1	4.0	0.018	0.038	0.025	0.026	3.25
	2	3.9	0.019	0.035	0.024	0.028	3.35

Phage in the control tubes was not so stable as one had hoped, falling to nearly 1/4 of the initial titre at 69 h. However, the absolute counts for the 0.4 mg treatment were higher at 19 h than at 3 h. Moreover, very similar results were obtained with *H*-treated *T 2* whereas the surviving fractions of *T 2* given commensurate doses of ultra-violet or X-radiation behaved in the same way as controls.

**Discussion.** There seems little doubt that the recovery of bacteria from treatment by mustard gas is metabolically mediated. Our colleague Dr. D. Rosen has derived a mathematical expression to describe the spontaneous recovery expected from uncoupling of cross-links by base release as described by Brookes and Lawley, making the additional assumption that base release at both ends of such a link would be secondarily lethal. The degree of recovery observed (Table 1) falls considerably below the expectation from Rosen's equation, but it would be idle to speculate on the reasons for this at present. On the other hand, the recovery observed with bacteria is greater than could be accounted for in this way.

At this stage the most profitable supposition is that recovery occurs by excision of the damaged DNA regions followed by synthetic repair in a manner analogous to that envisaged by Setlow and Carrier<sup>2</sup> for recovery from ultra-violet lesions. However, in the interpretation of our results we are confronted with two additional difficulties. First, recovery appears to occur in the absence of an energy source and, secondly, we are concerned with a lesion involving both strands of the DNA at points set apart by but a single nucleotide.

It is to be expected that the excision of a damaged region would be accomplished exothermically and would therefore be fully able to proceed in buffer. On the other hand, it is unlikely that synthetic replacement could so proceed unless the cells, albeit washed and diluted, retain a reservoir of nutrients sufficient for this purpose. It could be that only the excision stage in fact occurs in the buffer but that on transfer to broth agar there is still a sufficient lag during which replacement can be accomplished prior to DNA replication. If this were the case it would need to be supposed that the longer lag occurring on minimal medium was sufficient to permit both stages of recovery to occur on the plate.

With regard to considerations of how the excision might come about, a number of possibilities come to mind involving either uni- or bi-lateral excision; if excision were unilateral, repair would not in theory be essential since monofunctional alkylation does not necessarily impair the replicative function. What does seem to be excluded is simultaneous bilateral excision since, although full pairing information would be retained, the DNA would surely lose its linear integrity. These considerations are best left until more experimental material is available; at the time of writing we learn privately from Drs. Brookes and Lawley that they have observed a marked loss of label from the DNA of <sup>35</sup>S mustard gas-treated *E. coli B/r* during post-treatment cultivation in full (glucose-containing) *M-9* medium.

One further consideration. We have asked ourselves whether there is any connexion between the ability to recover and the tendency to form filaments or not during cultivation in nutritive media after an exposure to mustard or radiation. Strain *B* forms long filaments in broth after biologically mild doses of *H* or *HN 2* (corresponding to an initial survival of 50 per cent or more); it does so even more markedly after full recovery in buffer. Strain *B/r* does not filament in either circumstance.

This work is preliminary in nature and indicates a number of lines for future experiment; in particular, attention should be directed to the influence of enzyme inhibition on recovery.

## IMMUNOELECTROPHORETIC ANALYSIS OF *Ascaris suum* ANTIGENS

By J. TORMO and A. CHORDI

Department of Microbiology, University of Navarra, Pamplona, Spain

MUCH is already known about the analysis of *Ascaris* antigens by agar double diffusion. Kent<sup>1</sup> has found in the aqueous extract of *Ascaris* at least four active antigens, using Ouchterlony method. Soulsby<sup>2</sup> has shown by double diffusion that each fraction is a mixture of antigenic components. Kagan *et al.*<sup>3</sup> find 4-11 bands by double diffusion agar in tube, and more recently Huntley and Moreland<sup>4</sup> found a similar number of bands. Kagan *et al.*<sup>5</sup> have shown that the number of immunodiffusion bands of each antigenic fraction varies according to the chosen physico-chemical method of fractionation.

However, immunoelectrophoretic investigation of all the components in *Ascaris* antigens are not, to our knowledge, available. This article describes an analysis of the proteins of seven antigen preparations of *Ascaris suum* as revealed by immunoelectrophoresis. It was the purpose of this work to determine the complexity of each antigen preparation, and to determine which antigenic components were the most active in serological diagnostic tests.

Besides perienteric fluid, two saline extracts of *Ascaris suum* have been studied. One antigen (Z) was obtained following the technique of Oliver-González<sup>6</sup>, and the other saline extract (ETSA) was prepared with a constant content of protein nitrogen. Four protein-polysaccharide antigens have also been examined. One (V) was obtained according to Fuller's method<sup>7</sup>, and the other three were prepared by the technique of Oliver-González<sup>6</sup> modified by Kagan<sup>8</sup>. Antigen X was deproteinized only by heat, antigen T was also subject to several physico-chemical procedures, and antigen Y was obtained by precipitation with acetone of the saline extract. Antigens prepared from proteins of host (pig serum) and intestinal contents have also been studied, to determine whether there were any antigenic similarities between the components of the *Ascaris* and those of the host.

Antisera of rabbits immunized with perienteric fluid or with pig serum, and infected orally with eggs of *Ascaris suum*, were used to develop the immunoelectrophoretic patterns. Immunoelectrophoresis was carried out according to the micromethod described by Scheidegger<sup>9</sup> with light modifications as previously described<sup>8</sup>.

The lines of precipitation produced when several antigen preparations are subject to electrophoresis and then reacted with immunoserum anti-ETSA are shown in Fig. 1. In the drawings each arc with the same number belongs to the same antigenic component. Immunoelectrophoresis of ETSA developed with anti-ETSA showed 20 different components. Fig. 2 is a photographic reproduction of this system.

Fig. 3 shows the bands obtained with the anti-perienteric fluid immunoserum. Fewer bands were found with all the antigen preparations even with homologous perienteric fluid. Apparently the perienteric fluid showed less power of stimulating antibodies than the

standardized ETSA antigen. The results of immunoelectrophoresis of antigen preparations of *Ascaris suum* developed against the serum of an experimentally infected rabbit and developed against a serum from a patient suffering from visceral larva migrans are shown in Fig. 4. ETSA antigen was that which showed more bands (six) with the anti-*Ascaris* serum of an infected rabbit. This antigen only showed 3 bands with the human diagnostic serum.

Fig. 1. Immunoelectrophoretic patterns of total saline extract (ETSA), total antigen of Oliver-González (Z), perienteric fluid (LP), and two protein-polysaccharide antigens of Oliver-González and Kagan (Y and X), developed by immunoserum anti-ETSA.

Fig. 2. Photographic illustration of immunoelectrophoretic pattern between antigen preparation ETSA and anti-ETSA immunoserum

Anti-*Ascaris* sera do not give reaction by Ouchterlony and immunoelectrophoresis with the protein components of the host (pig serum) nor with those of its intestinal content. Nor was there any reaction between the antigens of *Ascaris* with the serum anti-protein of the host. It was clear that the antigen preparations of *Ascaris* used had no protein components of the host nor of its intestinal content. In the immunoelectrophoresis of pig serum, 24 different components of the host were identified.

Fig. 3. Immunoelectrophoresis of antigen preparations ETSA, Z and LP developed by immunoserum anti-LP

Fig. 4. Immunoelectrophoresis of antigen preparations developed against the serum of an experimentally infected rabbit (anti-AL) and developed against a serum from a patient with visceral larva migrans

Table 1. ANTIGENIC COMPONENTS IN THE IMMUNOELECTROPHORESIS OF *Ascaris* ANTIGEN PREPARATIONS AND OF ANTIBODIES TO THE ANTIGENIC COMPONENTS OF *Ascaris* FOUND IN INFECTED RABBITS AND IN A PATIENT WITH VISCERAL LARVA MIGRANS (VLM)

believe, may be the cause of this absence of reaction in the immunodiffusion techniques.

Table 1 summarizes the results obtained during antigenic analysis by immunoelectrophoresis. In it are listed the antigenic components found in *Ascaris* antigen preparations in order of appearance from the cathode to the anode side of the immunoelectrophoresis slide. In addition, the electrophoretic mobility zone relative to pig serum, the staining characteristics (when determined), the antigenic components of the several preparations and the antibodies to the antigenic components of *Ascaris* found in the serum of infected rabbits and in the human serum from a patient with visceral larva migrans are also listed.

The components for serological diagnosis are those against which the antibodies in human patients or in infected animals are produced. In case of ascariidiosis, and having in mind the results of this investigation, the selected antigen preparations would be those that present the antigenic components Nos. 6, 9, 10, 13, 14, 17 and 20, since experimentally infected rabbits, and human patients with visceral larva migrans, produced large amounts of antibodies against these antigenic components.

Thus, the protein polysaccharide antigen X deproteinized by heat is not a good antigen preparation for serological diagnosis since it lacks 6 of 7 principal antigenic components for serodiagnosis. Nor is the antigen Y good for serodiagnosis, because it lacks five of the principal antigenic components for serodiagnosical work.

On the other hand, the perienteric fluid had all but one, and both saline extracts showed all the important antigenic components. They are therefore the most thoroughly investigated antigens for a high sensitivity in the serological tests, since they are rich in important antigenic components for serodiagnosis.

## INHIBITION OF INTERFERON SYNTHESIS AND STIMULATION OF VIRUS PLAQUE DEVELOPMENT IN MAMMALIAN CELL CULTURES AFTER ULTRA-VIOLET IRRADIATION

By JAQUELINE DE MAEYER-GUIGNARD\* and EDWARD DE MAEYER

Department of Virology, Rega Institute, University of Louvain, Louvain, Belgium

THE polycyclic carcinogenic hydrocarbons 3-methylcholanthrene, benzo(a)pyrene and 7,12-dimethylbenzo(a)anthracene inhibit interferon synthesis and stimulate Sindbis virus plaque development in rat embryo cell cultures<sup>1-3</sup>. Chemically related but non-carcinogenic compounds, such as benzo(e)pyrene and pyrene, have no enhancing effect on virus plaque size<sup>3</sup>. This increase in the spread of viral infection under an agar overlay, and the decrease in interferon synthesis in cultures with fluid medium, obtained with chemical carcinogens, prompted us to look for similar effects with carcinogens of a completely different nature. The effect of ultra-violet irradiation, known to exert carcinogenic activity<sup>4-6</sup>, was therefore investigated.

Secondary cultures of rat embryo cells, grown in plastic Petri dishes in a humidified atmosphere of 5 per cent CO<sub>2</sub> in air at 36.5° C, were used. The origin of these cells, preparation of the cultures and composition of the culture medium have been previously described in detail<sup>1</sup>. Cultures were irradiated only when complete monolayers had been obtained, usually 4-5 days after seeding. All irradiations were carried out with a germicidal mercury low-pressure vapour lamp (Westinghouse Sterilamp G36T6-L) with maximal emission at 2537 Å. Cultures were irradiated at a distance where the energy received was 60 ergs mm<sup>-2</sup>/sec, as measured with a Latarjet dosimeter<sup>7</sup>. Before irradiation, the growth medium was replaced by 5 ml. of phosphate-buffered saline; the average thickness of the layer of fluid covering the cell sheet was 0.9 mm. Immediately after irradiation the phosphate-buffered saline was removed, and 2 ml. of a Sindbis virus suspension, calculated to give an average of 20 plaques per dish, was added. The virus was left to adsorb to the cells for one hour, after which the inoculum fluid was removed, and 15 ml. of a nutrient agar overlay was added to each plate. The Sindbis virus

used and the composition of the agar overlay have been described in detail<sup>1</sup>. One day before counting and measuring the plaques, 10 ml. of a second nutrient overlay of the same composition as the first, but supplemented with neutral red, was added to each culture. Table 1 presents some results of an experiment where the development of plaques in control and irradiated cultures was followed for several days. It can be seen that there was a significant increase of virus plaque size in cultures previously exposed to ultra-violet rays (see also Fig. 1). The dose of irradiation enhancing plaque size did not exert any lethal effect on the cells when fully developed (5-day-old) cultures were irradiated, as measured by cell counts and uptake of the vital dye neutral red during the days following irradiation. However, if one-day-old cultures were irradiated, a 30 per cent decrease in growth rate was observed. A striking enhancement of Sindbis virus plaque size was afterwards also obtained in cultures of African green monkey (*Cercopithecus aethiops*) kidney cells irradiated for either 4, 8 or 16 sec (see Fig. 2).

The higher susceptibility to virus infection of mammalian cells under agar after ultra-violet irradiation resembles the effect we observed with some carcinogens. This does not necessarily imply that both phenomena are due to the same mechanism, and several possibilities can be envisaged. An increased cellular permeability for viruses, due to the irradiation, is conceivable; this would be in line with a hypothesis recently advanced<sup>8</sup>. It is

Table 1. AVERAGE SINDBIS VIRUS PLAQUE DIAMETERS IN CONTROL AND ULTRA-VIOLET-IRRADIATED RAT EMBRYO CELL CULTURES, 4 DAYS AFTER INOCULATION WITH THE VIRUS

Period of irradiation	Number of plaques measured	Average diameter in mm
Controls	27	4.4 (0.44)*
2 sec.	32	5.9 (0.36)
4 sec.	26	6.8 (0.40)
8 sec.	31	6.0 (0.44)

Fig. 1. Sindbis plaques in control and irradiated rat embryo cell cultures, four days after seeding. Left, control culture; right, culture irradiated during 4 seconds

Fig. 2. Sindbis plaques in control and irradiated monkey kidney cell cultures, seven days after seeding. Left, control culture; right, culture irradiated during 16 seconds

also conceivable that the enhancing effect on viral plaque formation is due to a general depression of the rate of cellular protein synthesis, caused by an impairment of cellular DNA function. Under such conditions, the synthesis of any cellular factor(s) directly or indirectly responsible for the limitation of the spread of viral infection under the agar would be temporarily or definitively decreased; ribosomal and mitochondrial function on the contrary would be left relatively untouched, and would remain available for synthesis of viral material. One factor capable of limiting viral infection is interferon<sup>9</sup>, and it was therefore of interest to examine the effect of ultra-violet irradiation on its synthesis, especially in view of the decreased synthesis observed with chemical carcinogens.

Four secondary cultures of rat embryo cells were irradiated during 8 sec. Immediately afterwards, these cultures, together with four control cultures, were inoculated with Newcastle Disease virus, at a multiplicity of about 1 egg  $ID_{50}$  per cell. The virus was left to adsorb to the cells during 2 h, after which the excess inoculum was removed, and 20 ml. of maintenance medium was added to each culture. 44 h later all media were gathered. Portions of the media to be tested for interferon were then dialysed during 96 h against Sørensen buffer at pH 2, in order to destroy any living virus. The dialysed fluids were afterwards titrated for interferon activity, following a method previously described in detail<sup>1</sup>. The results of this titration are given in Table 2. It can be seen that irradiation of cells before addition of the virus completely inhibited interferon production, whereas a

Table 2. INTERFERON ACTIVITY OF FLUIDS DERIVED FROM IRRADIATED AND CONTROL CULTURES, AS EXPRESSED BY REDUCTION OF CHALLENGE VIRUS PLAQUES

		Dilution tested for interferon activity

	4	55	5	65	0

\* Each value represents the average plaque reading of four cultures.

† The average number of challenge plaques was 58.

considerable amount of interferon was produced in non irradiated control cultures. This interferon furthermore was completely inactive when tested in chick cells, which agrees with the species specificity described for interferon and rules out any interfering activity due to residual virus. In another experiment, not reported in detail here, an inhibition of interferon synthesis was observed in ultra-violet irradiated cultures subsequently infected with Sindbis virus. Virus yields, however, were the same in control and irradiated cultures.

The inhibition of interferon synthesis, and the increase of viral plaque size, both observed after ultra-violet irradiation, are perhaps provoked independently by the irradiation, or there might be a causal relationship between the inhibition of interferon synthesis and enhancement of plaque size.

Some indirect evidence in favour of the latter hypothesis was obtained in the following way. Use was made of a continuous line of rat cells, called 'DE40' cells, maintained in this laboratory since 1959. These cells are insusceptible to the antiviral activity of interferon, as described in detail elsewhere<sup>3</sup>. It was reasoned that if the increased plaque size observed after irradiation were due to an inhibition of interferon, there should be no increase of plaque size in 'DE40' cells, since these cells are insusceptible to interferon. In a preliminary experiment, it was established that the energy required to kill the 'DE40' cells was about the same as that needed to kill rat embryo cells. This experiment was carried out in order to have an indication of the relative susceptibility to ultra-violet irradiation of both cell systems. The influence of irradiation on plaque size was then investigated as follows. Four-day-old monolayer cultures of 'DE40' cells grown in plastic Petri dishes in an atmosphere of 5 per cent  $CO_2$  in air were irradiated during 10 or 15 sec; the energy received was 60 ergs  $mm^{-2}/sec$ . Immediately after irradiation a plaque assay with Sindbis virus was carried out, following the procedure described above. Five days later plaques were counted and measured. There was no difference either in plaque number or in plaque size between irradiated and control cultures (see Fig. 3). A second experiment carried out under similar conditions gave identical results.

Fig. 3. Sindbis virus plaques in control and irradiated 'DE40' cell cultures, five days after seeding. Left, control culture; right, culture irradiated during 15 seconds

The inhibition of interferon synthesis and the enhancement of virus plaque size after ultra-violet irradiation closely resemble the effects obtained with carcinogenic hydrocarbons under similar conditions. This suggests the existence of a common target site at some cellular level. It is known that ultra-violet irradiation can cause alteration of DNA<sup>8,10</sup>. Therefore it is possible that the inhibition of interferon synthesis as observed in irradiated cells is due to an impairment of cellular DNA function; it has indeed been shown that interferon synthesis is coded by the genome of the cell<sup>11</sup>. The possibility that inhibition of interferon synthesis by polycyclic carcinogenic hydrocarbons is the result of an interaction with the cellular genome should be considered.

## PREPARATION OF SYNCHRONOUS CELL CULTURES BY SEDIMENTATION

By PROF. J. M. MITCHISON and PROF. W. S. VINCENT\*

Department of Zoology, University of Edinburgh

A NUMBER of techniques for obtaining synchronous cell cultures have been worked out in recent years with the prime object of investigating the biochemical events of the cell cycle<sup>1</sup>. In most cases, the cells are subjected to a series of changes in their environment (for example, temperature, light or nutrients) which cause the culture to become synchronous. With a few cell systems, however, it has been possible to use another method which is different in principle. Cells at a particular stage of the cell cycle have been separated physically from a normal growing culture and then grown separately as a synchronous culture<sup>2-5</sup>. Separation methods tend to give a low yield, but have the merit that there is less likely to be a drastic change in cell metabolism during the process of synchronization.

We have developed another separation method which relies on differential sedimentation, and have used it to produce synchrony in fission yeast, budding yeast and *Escherichia coli*. In essence, the method consists of centrifuging cells from an exponentially growing culture through a sucrose gradient. Small cells, at the start of the cell cycle, move through the gradient more slowly than large cells, or clumps of cells, and can be separated off and grown as a synchronous culture. The main function of the sucrose gradient is to stabilize the column of liquid through which the cells sediment. It also provides a dense medium on top of which the initial cell suspension can be layered. It does not act as an equilibrium gradient since in time all the cells can be centrifuged to the bottom of the tube.

The details of the method are as follows:

(1) *Gradients*. Linear sucrose gradients are set up in straight-sided centrifuge tubes by means of a gradient machine<sup>6</sup>. The gradients should occupy 80-90 per cent of the volume of the tubes. We have used two sizes of tube—small ones (16 × 150 mm) with 15-ml. capacity and large ones (25 × 170 mm) with 80-ml. capacity. A gradient from 2 per cent sucrose (w/v) at the top to 12 per cent at the bottom is sufficient to stabilize the small tubes, but the large tubes need a 10-40 per cent gradient. It might be possible to use shallower gradients with careful régimes for starting and stopping the centrifuge or with sector tubes<sup>7,8</sup>. The sucrose was commercial sugar and in some cases was made up in a minimal medium rather than water. Once made, the gradients are stable for several days but they should be kept cool unless they are sterile.

(2) *Loading*. Cells from a culture of exponential growth are centrifuged to give a concentrated suspension. This suspension is then layered carefully on top of a gradient. We have used 0.5-1 ml. suspension for the small tubes and 2-5 ml. for the large tubes. As soon as the suspension has been put on, it should be stirred with a thin rod to mix it with the top of the sucrose until the milky layer of cells is about twice its original thickness. This tends

to produce an inverse gradient of cells at the top of the tube and hence prevents the formation of streamers of cells. We have tried loading with an inverse gradient of cells from a small gradient machine<sup>9</sup> but it does not give an improved separation. The number of cells that can be loaded will depend on the cell size. We have had good results from  $2 \times 10^{10}$  exponential phase cells of *Schizosaccharomyces pombe* in 4.7 ml. loaded on a large tube. This number of cells has a dry weight of about 0.7 g and would be produced by 670 ml. of a stationary phase culture ( $3 \times 10^7$  cells/ml.) or 4,000 ml. of an exponential culture ( $5 \times 10^6$  cells/ml.). It might be possible to increase the loading somewhat above this figure, though the cell suspension would become viscous and difficult to handle. The loading for an experiment could certainly be increased, however, by using tubes of larger diameter or, of course, by using several tubes.

(3) *Centrifuging*. The loaded gradients are centrifuged in swing-out buckets. The speed and time of centrifuging will depend on the cells, the gradient and the temperature. We used 500g for 10 min at 25° C for yeast, and 2,500g for 20 min at 12° C for *E. coli*. Cells sediment considerably faster at higher temperatures. During the centrifuging, the milky cell layer moves down the tube, broadening as it goes. It is best to stop when the layer has moved one-half to two-thirds of the way down. By this time there is often a pellet of clumped cells at the bottom. In the case of yeast, a compromise has to be reached about the temperature in the centrifuge. If it is too low, there is a risk of the temperature shock affecting the subsequent growth. If it is at the optimum growth temperature, and the gradient is heavily loaded, gas bubbles will be produced by the growing cells which will disturb the gradient.

(4) *Sampling*. After centrifuging, the top of the cell layer is removed by a syringe with a long needle (held in a clamp with a vertical screw movement) and suspended in fresh medium to produce a synchronous culture. The amount of the layer that is removed is again a matter of compromise. If the amount is large the yield is large, but the separation of small cells is less efficient and the synchrony of the resulting culture is poor. We have usually removed the top 5-20 per cent of the length of the layer. Since the top of the layer has a lower cell density than the rest of the layer, this gives a recovery of 1-5 per cent of the cells which were loaded originally. The point of the needle should be placed at the bottom of the region to be sampled because, in a density gradient, the liquid which is removed comes from above the needle point.

The cells that have been tested are given in Table 1, together with their growth media and temperatures. Two main sets of experiments were carried out using them. First, cell lengths were measured in a top sample from a gradient and in a control taken either from the rest of the cells in the gradient or from the initial suspension. The measurements were made on photographs of living

(a) *S. pombe*, 10–40 per cent gradient in 80-ml. tube loaded with  $2 \times 10^{10}$  cells from exponential culture ( $8.6 \times 10^8$  cells/ml.). Centrifuged at 500g for 10 min at 20° C. —, Top sample (0.5 per cent of cells loaded); — — —, control. (b) *S. cerevisiae*, 10–40 per cent gradient in 15-ml. tube loaded with  $6 \times 10^8$  cells from stationary culture ( $11 \times 10^8$  cells/ml.). Centrifuged at 200g for 6 min at 20° C. —, Top sample (top 10 per cent of cell layer); . . . , bottom sample (bottom 20 per cent of cell layer); — — —, control. (c) *E. coli*, 10–40 per cent gradient in 15-ml. tube loaded with  $2 \times 10^{10}$  cells from exponential culture ( $6 \times 10^8$  cells/ml.). Centrifuged at 2,500g for 20 min at 12° C. —, Top sample (2 per cent of cells loaded); — — —, control.

Fig. 2. Cell numbers in synchronous culture of *S. pombe*. 10–40 per cent gradient in 80-ml. tube loaded with  $3 \times 10^8$  cells from exponential culture ( $3.2 \times 10^8$  cells/ml.). Centrifuged at 500g for 10 min at 25° C. Top sample suspended in fresh medium.

Fig. 3. Percentage of cells with cell plates in synchronous culture of *S. pombe*. 10–40 per cent gradient in 80-ml. tube loaded with  $3 \times 10^8$  cells from exponential culture ( $2 \times 10^8$  cells/ml.). Centrifuged at 500g for 9 min at 25° C. Top sample (4 per cent of cells loaded) suspended in fresh medium.

cells in the case of the yeasts and of fixed and stained cells in the case of *E. coli*. Results for each kind of cell are shown as frequency histograms in Fig. 1. There is a definite separation of the smaller cells into the top sample, but it is by no means perfect. It is possible that a better separation might be obtained with some types of cell if the top layer were centrifuged again in a second gradient, but we have tried this with *S. pombe* and did not get an improved separation. It is likely that an accurate sizing

is impossible by this method because of the variations in density among cells of the same size. The ratio of standard deviation over mean for cell density in *S. pombe* is 0.12 (ref. 9). A stationary culture (without buds) was used for *S. cerevisiae* since measurements of cell length carry less meaning in growing cells of this organism. The separation in these roughly spherical cells was somewhat better than it was for the other two rod-shaped cells, as would be expected from the physical laws of sedimentation. A histogram for the bottom layer of *S. cerevisiae* is included in Fig. 1b, and it shows a preponderance of large cells. This also occurred with the bacterium and the fission yeast, but the biological picture in the lower layers here was complicated by the presence of lumps and of pairs of young cells which had not at that time separated.

In the second set of experiments, top samples from gradients were removed and suspended in fresh media. Their progress as synchronous cultures was followed by cell counting in haemocytometers with the yeasts (using the criteria of Williamson and Scopes<sup>10</sup> for *S. cerevisiae*) and by colony counting with *E. coli*. Fig. 2 shows an experiment with *S. pombe* where there are two, perhaps three, synchronous divisions. A criticism of it as a synchronous culture is that there is not an accurate doubling of numbers in the second step at 5 h. Another sample, however, was taken from the same gradient just below the top one and also followed, though it is not reproduced here. Its steps were not quite so steep but did show accurate

Fig. 4. Cell numbers in synchronous culture of *S. cerevisiae*. 10–40 per cent gradient in 80-ml. tube loaded with  $4 \times 10^8$  cells from exponential culture ( $2.9 \times 10^8$  cells/ml.). Centrifuged at 500g for 10 min at 25° C. Top sample (3 per cent of cells loaded) suspended in fresh medium.

Fig. 5. Colony counts from synchronous culture of *E. coli*. 10–40 per cent gradient in 15-ml. tube loaded with  $2 \times 10^{10}$  cells from exponential culture ( $6 \times 10^8$  cells/ml.). Centrifuged at 2,500g for 20 min at 12° C. Top sample (2 per cent of cells loaded) suspended in fresh medium.

Table 1

Organism	Medium	Growth temperature (°C)
<i>Schizosaccharomyces pombe</i> (N.C.Y.C. 132)	Minimal medium 'E.M.M.' <sup>11</sup>	32
<i>Saccharomyces cerevisiae</i> (commercial bakers' yeast)	Minimal medium 'E.M.M.' <sup>11</sup>	30
<i>Escherichia coli</i> K12AF <sup>-</sup>	Double strength 'Oxoid' nutrient broth	37

doublings. The remaining cells from the gradient (about 90 per cent of the cells which were loaded) were also resuspended and followed, but showed no signs of synchrony. Another method of following synchronous cultures in *S. pombe* is to count the number of cells showing cell plates. This is equivalent to a mitotic index, and, in a normal growing culture, about 10 per cent of the cells have cell plates. Fig. 3 shows a synchronous culture followed this way. There were four synchronous divisions which lasted until the culture ran into the stationary phase after 10 h. Fig. 4 shows an experiment with *S. cerevisiae*. The steps were not quite so sharp as those with the fission yeast and there was a slight initial lag. The culture was in the stationary phase at 6 h. Fig. 5 shows an experiment with *E. coli*. There were three synchronous divisions and signs of a fourth. The growth rate appears to accelerate for the first 75 min, which might be due to cellular changes occurring during the period of 45 min between collecting the initial log phase culture and setting up the synchronous culture.

This is not a perfect method for making synchronous cultures since the separation of small cells is incomplete and the initial steps in the cell number curves are not vertical. Nor is it as good as the best of the existing methods. For example, the budding yeast synchrony in Fig. 4 is worse than that produced by the method of Williamson and Scopes<sup>10</sup>. It does, however, have many advantages. It is simple, and requires little in the way of apparatus except a centrifuge and a gradient machine. It is relatively quick compared with many other methods. The whole procedure, including collecting, but excluding the preparation of gradients, takes 20–80 min. It gives a reasonably large yield. With a loading of  $2 \times 10^{10}$  yeast

cells and a recovery of 5 per cent, it gives a 200 ml. synchronous culture. It works with exponential phase cells and so avoids the criticism that can be made of methods which start with stationary cells—that the initial period of growth represents recovery from the stationary phase. Above all, it is a method which should work with a wide variety of cells. We have tried it with three kinds of cells of different shapes and sizes, and we have little doubt that it will work with many other types. Good size separations have already been obtained with strain *L* mouse cells by Dr. D. H. Bishop and Dr. R. Sinclair in this laboratory, and work on this cell system is in progress. With cells which are affected by the osmotic pressure of sucrose, it should be possible to substitute gradients of protein, dextran or 'Ficoll'. Dextran gradients have been used by Lieblova *et al.*<sup>8</sup> to separate budding yeasts with different numbers of bud scars. Since dextran is not metabolized, these gradients are not disturbed by gas bubbles. It is more difficult, however, to make steep gradients because concentrated dextran solutions are very viscous.

We thank Dr. D. H. Bishop for his help in carrying out the experiments with *E. coli*, Prof. M. M. Swann for valuable discussions, and Mr. J. Creanor for his help. One of us (J. M. M.) was the recipient of a special research grant from the Department of Scientific and Industrial Research, and the other (W. S. V.) the holder of grant GM11480 from the National Institutes of Health, U.S. Public Health Service.

## BEHAVIOUR OF CERTAIN MARINE ORGANISMS DURING THE SOLAR ECLIPSE OF JULY 20, 1963

By DR. RICHARD H. BACKUS, ROBERT C. CLARK, jun., and ASA S. WING

Woods Hole Oceanographic Institution, Woods Hole, Mass.

THE effect of solar eclipses on animal activity is the subject of a literature which, though not extensive, has ancient beginnings. Much of it has been summarized recently by Cloudsley-Thompson<sup>1</sup>, who concludes: "Some animals show exogenous rhythms, others are more markedly endogenous". That is, some animals engage in crepuscular activities during the eclipse, while others continue their natural mid-day ones. In this literature only the briefest attention has been directed to marine organisms.

This article reports the similar behaviour of two sorts of phylogenetically unrelated marine organisms during the solar eclipse of July 20, 1963. Observations were made of so-called 'deep scattering layers' and of the bioluminescence of certain planktonic micro-organisms.

In those cases where sound-scattering from the deep scattering layers has been examined critically, using broad-band sound sources and spectrum analysis, a gas-bubble-bearing sound scatterer is indicated<sup>2</sup>. Since mesopelagic fishes with swim-bladders are such bubble-bearers, since many of these fishes correspond generally in their vertical and geographic distributions with the deep-

scattering layers<sup>3</sup>, and since such fishes may be taken by nets towed in deep-scattering layers, it is widely accepted that such animals are indeed the agents responsible for many or most of the deep-scattering layers observable throughout the oceans of the world. Certain other gas-bubble bearers among the plankton and nekton cannot be excluded, however. For example, Barham<sup>4</sup> has made certain observations from the bathyscaphe *Trieste* off Monterey, California, suggesting that the bubble-bearing siphonophore *Nanomia bijuga* may be responsible for a deep-scattering layer there. Characteristic of most deep-scattering layers is the upward vertical migration, the extensive and rapid part of which begins about sunset, and the subsequent retreat to the depths that begins with morning twilight (see recent reviews of the deep-scattering layer 'problem' by Hersey and Backus<sup>5</sup> and by Boden<sup>6</sup>).

Similar behaviour (in that it is apparently light-controlled) has been reported by us<sup>7</sup> for certain bioluminescent micro-organisms at the sea surface, both in coastal waters and on the deep ocean. These organisms, taken to be dinoflagellates chiefly, are luminescent at night, but mainly not so during the day. The change from the one

condition to the other and back occurs quickly at sunrise and sunset.

The literature on the effects of solar eclipses on animal activity can be taken to be a special part of a now massive literature concerning circadian endogenous rhythms in a host of plants and animals (much of which is summarized by Bunning<sup>8</sup>, Cloudsley-Thompson<sup>1</sup>, and in *Biological Clocks*<sup>9</sup>). Sweeney and Hastings<sup>10</sup>, for example, show that the dinoflagellate *Gonyaulax polyhedra*, when kept in constant dim light, has a cycle of luminescence-non-luminescence close to 24 h in period. In fishes, it has been demonstrated, at least, that several species orient with respect to the Sun while allowing for its changing azimuth, thus demonstrating their perhaps endogenous ability to measure the passage of time<sup>9</sup>.

Are the vertical migrations of the deep-scattering layers and the diurnal cycle of luminescence in dinoflagellates events principally or wholly under the control of the exogenous factor of light, or are they controlled, or modified, to a large extent by endogenous rhythms? In the scattering layer case, the answer has already been suggested by Hersey and Moore<sup>11</sup>, who detected, during the daytime, the beginnings of an upward migration of a shallow (about 50 fathoms) scattering layer during the passage of "a particularly heavy rain squall". In similar circumstances we have observed a tendency for the bioluminescent activity of dinoflagellates to increase. But events such as passing rain squalls are not sufficiently dramatic reducers of sunlight to answer the question satisfactorily—a solar eclipse is.

Scattering layer observations were made from R.V. *Chain*, hove to about 200 miles south of Woods Hole, Mass. (37° 38' N., 69° 28' W.), in slope water in 2,105 fathoms. The observations were in the form of echosoundings made with an Alden Electronics precision graphic recorder and an EDO UQN-1b transducer and electronics (operating frequency, 12 kc/s). The depths

Fig. 1a (top), vertical distribution of three scattering layers and surface light intensity during the solar eclipse of July 20, 1963; b (bottom), same on a normal afternoon offered for comparison with 1a

Fig. 2a, Bioluminescent flashing and surface light intensity during the solar eclipse of July 20, 1963; b, The same as 2a for the normal afternoon of July 21, 1963

plotted in our figures represent the mid-point of the densest portion of each layer and are based on a sound velocity of 4,800 ft./sec. Light readings were made using a Sekonic Auto-Leader model L-38 light-meter with 8 times neutral density filter; pointing it directly at the Sun from a point 60 ft. above the sea-surface. This light meter was calibrated against a General Electric radiation meter model 8DW 60Y2. The minimum light intensity read (very near the middle of the eclipse) was 0.1 g. cal/cm²/min. Time of mid-eclipse was 1652 E.S.T.; eclipse duration, 125 min (Nautical Almanac Office<sup>12</sup>). Ninety per cent of the Sun's diameter was obscured at mid-eclipse when the altitude of the Sun was about 22°. Sunset was at 1858 E.S.T. The sky was generally clear (a few high clouds) and the sea calm.

Bioluminescence observations were made at the entrance to Eel Pond, a sea-level, tidal pond opening on to Great Harbor, Woods Hole, by pumping water through a darkened chamber that was inspected by a photomultiplier tube. This tube was connected by appropriate circuitry to a counter that tallied and printed out counts of bioluminescent flashes every 5 min<sup>7</sup>. Light readings, not reducible to absolute levels, were continuously recorded with four International Rectifier selenium photocells (B2) connected in parallel to a Rustrak recorder. Calculated time of mid-eclipse was 1645 E.S.T., eclipse duration about 127 min<sup>12</sup>. Ninety-four per cent of the Sun's diameter was obscured at mid-eclipse when the altitude of the Sun was about 28°. Sunset was at 1914 E.S.T. The sky was overcast.

Scattering layer observations made during the eclipse, together with light readings, are plotted in Fig. 1a. We have no comparable observations at the same location for a non-eclipse day close in time, but data for a normal afternoon (August 14, 1959) from a nearby locality (38° 40' N., 68° 33' W.) are shown, together with surface light readings, in Fig. 1b. What often has been taken for a single thick scattering layer in this region generally is resolvable, with a good echo-sounder, into three or four separate layers. Both Figs. 1a and 1b show three such sub-layers, save in the late part of Fig. 1a, where, after the ship got under way at 1740, only the best developed element was detectable above background noise. It can-

Fig. 3. The same as 2a and 2b for the normal morning of July 21, 1963

be seen that on the day of the eclipse a greater than normal rate of ascent of the layers began about 20 min after the eclipse commenced. The ascent continued until about 5 min after mid-eclipse. During this period the average rates of ascent for the three layers were 1.8, 1.6 and 2.1 m/min. With the uncovering of the Sun and increasing light the layers descended, but not so rapidly (at average rates of 0.95, 0.6 and 0.9 m/min) as they had ascended with decreasing light and not reaching, for comparable light levels, the depths they held while the Sun was being obscured.

Unfortunately, the light readings could not be continued throughout the eclipse period or after it, but the last three readings (covering the period 1720–1730) show the light level to have been unchanging. The upper two layers continued their descent during this period and for 10 min afterwards (after which time they were no longer distinguishable, as noted earlier). The deepest layer essentially stopped its descent when the light stopped increasing. After about 20 min this layer began again to ascend. During the period of 1.25–0.25 h before sunset the layer rose at a mean rate of 1.3 m/min (Fig. 1a). The rates of ascent during the like period on August 14, 1959, for the three layers shown (Fig. 1b) were 0.4, 0.6 and 0.6 m/min.

The bioluminescence observations made during the eclipse are plotted together with light readings in Fig. 2a. Similar observations for the like period on the following day, July 21, 1963, are shown in Fig. 2b. Although observation did not begin before the beginning of the eclipse, it can be seen that flash counts were normal for the time of day until about the 5-min period ending at 1635 E.S.T., or about 50–55 min after the start of the eclipse and about 10–15 min before maximum eclipse. The light level at this time was about that observed on a normal day when the flash count begins to increase with the approach of sunset. Note, that is, that the first

intersection of the light and flash-count curves on July 20 (Fig. 2a) and the intersection for July 21 (Fig. 2b) both occur at about the same point on the ordinates. The maximum flash count on July 20 occurred for the 5-min period beginning at 1655 E.S.T., the time of minimum light intensity, but 10 min after the time of mid-eclipse. That the time of minimum light intensity was not coincident with the time of mid-eclipse probably is due to the variable, and at times heavy, cloud cover. With the increase in light, flash counts diminished rapidly, but, for given light levels, never decreased during the mid-eclipse-to-sunset period to the levels observed before mid-eclipse. Note, that is, that the intersection of the light and flash-count curves occurs at a higher point on their ordinates after mid-eclipse than before it (Fig. 2a). This hysteresis, higher flash-counts at a given light level with increasing light than with decreasing light, is observed also when normal sunrise (Fig. 3) and normal sunset (Fig. 2b) are compared, but here the effect is somewhat greater than in the eclipse situation.

In summary, we can say that both the scattering layer organisms and the bioluminescent organisms responded to the eclipsing Sun much as they normally respond to the setting Sun. Their behaviour from mid-eclipse to eclipse end resembled dawn behaviour. The response of these organisms to the change from decreasing light to increasing light near mid-eclipse was rapid. Thus, it appears that the exogenous factor of changing light largely controls the behaviour examined in these organisms, overriding such endogenous rhythms as may exist.

This work was supported by the National Science Foundation (grant NSF GB-543), the Office of Naval Research (contract Nonr-2196(00)), the Atomic Energy Commission (contract AT 20-1 1918), and by a Woods Hole Oceanographic Institution summer student fellowship to one of us (R. C. C.). Dr. Joseph Ashbrook, technical editor of *Sky and Telescope*, kindly provided the data relating to Sun coverage and altitude at mid-eclipse for the two pertinent locations. We thank G. L. Clarke, M. Blumer and J. B. Hersev for their advice.

## INFLUENCE OF PARTICLE SIZE ON DECOMPOSITION OF RED ALDER AND DOUGLAS FIR SAWDUST IN SOIL

By J. L. NEAL, jun., PROF. W. B. BOLLEN and DR. K. C. LU

Department of Microbiology, Oregon State University, and Forestry Sciences Laboratory, Forest Service, U.S. Department of Agriculture, Corvallis, Oregon

**I**NTENSIFIED use of sawdust and other wood wastes as soil conditioners, especially in the Pacific north-west, has prompted a number of workers<sup>1,2-5</sup> to investigate the effects of various types of sawdust and bark mulches on soil microbial activity and plant growth. Bollen and Glennie<sup>7</sup> reviewed fundamental principles and factors associated with the use of wood wastes on the soil and the

resultant effects on microbial activity. Although particle size, including its influence on surface/volume ratio, undoubtedly affects the rate of decomposition and humification, investigations to determine this have been few. Allison and Cover<sup>1</sup> found that fine sawdust of mesh size 4–6, 6–10, and 10–20, incubated 106 days in a loam soil, respired 36.5, 42.8, and 43.6 per cent respectively of the

total carbon. The rate of oxidation of sulphur in soils has been shown to increase even more rapidly as particle size decreases<sup>17</sup>. In these and similar reports by others the size of sawdust used is given in terms of sieve mesh passed or merely as finely ground. This article reports the effect of finer particle sizes of wood on their rate of decomposition in soil.

Samples of red alder and Douglas fir sawdust in four particle size ranges of from approximately  $700 \times 3,200\mu$  to  $1.6 \times 1.7\mu$ , as viewed in two dimensions under the microscope, were obtained through the courtesy of Dr. D. W. Glennie and J. L. Ricard, Forest Research Center, Corvallis, Oregon. Analysis of the various sawdust particles is shown in Table 1. Although it is not possible to arrive at exact surface-to-volume relationships from the two-dimensional measurements, it is obvious that progressive reduction in size does increase the relative surface exposure. In addition, it must be borne in mind that subdivision of a rod into more rod-shaped particles has much less effect in increasing surface than does subdivision of a cube or sphere into more cubes or spheres.

Table 1. ANALYSIS OF RED ALDER AND DOUGLAS FIR WOOD PARTICLES

Size group	Mean size* ( $\mu$ )	Distribution of shapes Polyhedra (%)	Spheroids (%)	Total surface of addition to Warburg flasks† ( $\mu^2$ )	Total carbon (%)	Total nitrogen (%)	C/N
Red alder							
1	$660 \times 3,120$	90	10	$5.0 \times 10^3$	47.5	0.105	452
2	$106 \times 318$	54	46	$3.4 \times 10^3$	43.3	0.100	430
3	4.0	—	100	$3.2 \times 10^{11}$	44.9	0.103	436
4	1.8	—	100	$3.5 \times 10^{11}$	46.3	0.095	487
Douglas fir							
1	$725 \times 3,540$	90	10	$4.0 \times 10^3$	48.7	0.053	919
2	$105 \times 280$	73	29	$2.1 \times 10^3$	44.5	0.055	809
3	4.4	—	100	$1.6 \times 10^{11}$	47.4	0.050	948
4	1.6	—	100	$2.9 \times 10^{11}$	48.5	0.060	808

\* Lateral dimensions as viewed under microscope.

† Assuming thickness of particles to be similar to width.

Pertinent also is the content of cellulose and lignin. Representative analyses are given in Table 2. Although these data were obtained with fresh sawdust, the values for holocellulose and lignin may reasonably apply to the wood used for the Warburg experiments despite the fact that the particles were prepared from kiln-dried alder boards and stored Douglas-fir sawdust. On the other hand, the percentages of carbon and especially of nitrogen vary with age, source and storage of sawdust. In all cases, however, alder is characterized by higher nitrogen and narrower C/N ratio; alder also is higher in pentosans and lower in  $\alpha$ -cellulose.

Table 2. CELLULOSE AND LIGNIN IN FRESH SAWDUST FROM RED ALDER AND DOUGLAS FIR\*

	Holocellulose (%)	Klasson lignin (%)	Carbon (%)	Nitrogen (%)	C/N
Red alder	72.06	23.10	49.84	0.87	135
Douglas fir	64.50	27.57	51.51	0.12	429

\* On basis of unextracted dry wood.

25-g portions, oven-dry basis, of Chehalis silt loam soil which had been sieved through a 10-mesh screen were used in 125-ml. Warburg flasks. Analysis of this soil gave a pH of 6.7, 0.183 per cent total nitrogen, and 2.28 per cent total carbon. Red alder and Douglas fir sawdust of the various particle size ranges were mixed at rates equivalent to 2,000 p.p.m. carbon before addition to the flask. These additions ranged from 103 to 116 mg according to carbon content. Water content was then added to adjust moisture to 27.6 per cent, which was 50 per cent of the water-holding capacity, corresponding to approximately one-half of the field capacity. 1 ml. of 20 per cent potassium hydroxide was added to the centre well fitted with fluted filter to absorb carbon dioxide. Duplicate flasks of each treatment were attached to calibrated manometers and placed in a constant-temperature water-bath held at 30° C. The flasks were allowed to equilibrate for 5 h before the manometers were closed. Oxygen uptake was

observed for 85 h. Calculations were made according to Webley<sup>21</sup>. Carbon dioxide evolution and respiratory quotient were not determined because several investigators<sup>10,16,18</sup> have indicated possible unreliability of this procedure in short-term manometric experiments with soil.

Because some reports<sup>13,14</sup> have shown a stimulation of cellulose-decomposing micro-organisms when inorganic nitrogen is added, while others<sup>2-7,9</sup> seem to indicate that nitrogenous additions depress decomposition of cellulose, lignin, and resin substrates, the experiment was repeated with the addition of ammonium nitrate. The amount used in each case was sufficient to bring the C/N ratio of the added materials to 20/1, which is generally considered optimum for decomposition. Appropriate controls of soil only were included in each experiment.

In flasks the contents of which consumed large volumes of gas, the manometers were opened to the atmosphere and reset to the 150-mm reference point. Experiments by Gilmour *et al.*<sup>11</sup> indicate that normal uptake of oxygen starts immediately after re-setting the fluid level. This was found to be true in our experiments. During the 85-h respiration period there were no indications of oxygen depletion in any of the flasks, as would be readily shown by cessation of oxygen consumption. The results given are means for duplicate treatments.

The comparative rates of oxidation of the various sawdust particle sizes are presented in Figs. 1 and 2. The results show a definite parallelism between the particle size and microbial activity; the smaller the particle, the greater the oxidative rate, as evidenced by oxygen

Fig. 1. Oxygen uptake by different size-groups of red alder wood particles in soil. Average particle size: 1,  $725 \times 3,540\mu$ ; 2,  $105 \times 280\mu$ ; 3,  $4.4\mu$ ; 4,  $1.6\mu$ .

Fig. 2. Oxygen uptake by different size-groups of Douglas fir wood particles in soil. Average particle size: 1,  $660 \times 3,120\mu$ ; 2,  $106 \times 318\mu$ ; 3,  $4.0\mu$ ; 4,  $1.8\mu$ .

consumption. Particles of  $1.7\mu$  mean diameter gave the highest rate of oxygen uptake for both Douglas fir and red alder, followed in order by the mean sizes of  $4.2$ ,  $106 \times 300$ , and  $700 \times 3,200\mu$ . The increased rates of oxidation for the smaller sizes may be due in part to the increased surface in relation to volume and in part to rupturing of the lignin-cellulose bonds by the mechanical preparation of the smaller particles<sup>15</sup>. An additional advantage attributable to smaller size may be a more extensive distribution of particles in the soil mass, thus mechanically increasing exposure to micro-sites of biological activity.

The two smaller size groups of red alder sawdust (Fig. 2) were more extensively decomposed at 85 h than the Douglas fir of comparable size. However, the rate of oxidation of the red alder was greater only after 50 h. This suggests a possible difference in chemical constitution, or a difference in physical structure and exposure resulting from the milling process. An opposite effect was observed with the two larger particle sizes.

Although decreasing the particle size of the sawdust by approximately 3,000-fold increased the oxidation rate, the effect was not as pronounced as could be expected from surface/volume relationships alone. Because the reduction in size was by prolonged ball-milling, some localized heating occurred. This may have caused some polymerization of chemical constituents and possibly a resultant decrease in susceptibility to oxidation. Nevertheless, it was found that the wood particles described in Table 1 were more extensively and rapidly available to solvent extraction as particle size decreased<sup>12</sup>. Presumably this size reduction would also render these components more susceptible to microbial oxidation.

Pew *et al.*<sup>16</sup> found that 95 per cent of the carbohydrate could be removed rapidly by cellulytic enzymes if wood particles were ground to  $1\mu$  or less in a cooled vibratory ball mill. This, with other evidence<sup>15</sup>, indicates that a three-dimensional lignin network probably surrounds the cellulose polymers in wood. Such an encrusting lignin framework may effectively hinder or prevent cellulases from attacking the carbohydrate chains. Because lignin is highly resistant to microbial decomposition and is susceptible to attack by only a few specialized micro-organisms<sup>19,20</sup>, only wood particles ground small enough to disrupt most of the ligneous encrustations would expose more cellulose and permit more rapid decomposition.

The addition of ammonium nitrate with the various sawdust sizes did not stimulate oxygen uptake (Figs. 3 and 4). Comparison of the apparent oxidative rates with and without the nitrogen addition indicates that in some cases a repression occurred. The inclusion of ammonium in the nitrogen source eliminated the possibility that some

Fig. 4. Oxygen uptake by different size-groups of Douglas fir wood particles with nitrogen added in form of ammonium nitrate in soil. Average particle size: 1,  $660 \times 3,120\mu$ ; 2,  $106 \times 318\mu$ ; 3,  $4.0\mu$ ; 4,  $1.8\mu$ .

cellulose decomposers would be unable to utilize the nitrogen because of inability to synthesize nitrate reductase. It seems doubtful that a salt effect occurred due to accumulation of nitrates as suggested by Allison *et al.*<sup>2</sup>; likewise, the small amount of ammonium nitrate added to the soil, less than 0.03 per cent, could have little osmotic effect on the soil microflora. On the other hand, added ammonium nitrate may have relieved the microbes from the necessity of decomposing nitrogenous soil organic matter for their nitrogen requirements, thus decreasing the overall oxidative rate, even though the added sawdust may be more extensively attacked. In macro-respiration experiments with nine species of hardwood, not including alder, Allison *et al.*<sup>3</sup> found that in 60 days, 30 per cent of the carbon was released as carbon dioxide in the absence of fertilizer nitrogen, and 45 per cent in its presence. Comparison of Figs. 1 and 2 indicates that the addition of ammonium nitrate with the red alder wood strongly depressed uptake of oxygen in all cases after 10 h. A similar, but less marked, effect occurred with Douglas fir. An increase in evolution of carbon dioxide from organic matter of wide C/N ratio apparently will not result from addition of mineral nitrogen if available nitrogen in the soil is sufficient to care for microbial requirements.

The results indicate, within limits of the experimental method, that when sawdust is added to soil the resultant influence on microbial activity is largely dependent on the size of the particles.

## LETTERS TO THE EDITOR

## ASTRONOMY

**Disappearance of the Polar Cap on Mars in 1956 after a Solar Flare with Ejection of Particles**

THE reason for the extraordinary and sudden disappearance of the south polar cap on Mars during its perihelion opposition in 1956 due to outside influence, primarily that of solar activity, was considered at the time of the opposition<sup>1</sup>. It is only now that two such series of processes as the exceptionally important solar activity on the Sun towards the end of August with a large flare on August 31, 1956, of the Y type, connected with the emission of cosmic and sub-cosmic radiation<sup>2-5</sup>, and the extraordinarily frequent occurrence of intensive dust storms after August 20 with the disappearance of the polar cap on Mars during August 31–September 1, 1956 (refs. 1, 6–10), are being physically related.

The commencement of the extraordinary development on Mars was recorded at the observatory in Ondřejov, by P. Příhoda, who on the night of August 19–20 saw three projections on the terminator of the planet, obviously low clouds above Mare Australe, Argyre and Vulcani Pelagus. On August 22, Bronshten<sup>1</sup> and Sharonov<sup>10</sup> in the U.S.S.R. observed a pronounced lightening in colour in the Argyre region: this they interpreted<sup>11</sup> as being a snow (hoarfrost) deposit which was later covered with dust clouds. The formation of large light spots on the surface of Mars was found photographically by Pickering as long ago as April 9, 1890 (ref. 12), but no analogous phenomenon has as yet been observed on such a scale during this century. On the night of August 24–25, Sadil<sup>8</sup> at the Popular Observatory in Prague, as well as other observers in this region, observed a yellowish cloud, the brightness of which was comparable with a polar cap. On the following days the dust cloud spread further.

Up to September 28, 1956, the appearance of the cap was normal, but on the night of August 29–30 it became less clear, took on a yellowish tint and became bordered by an unusually contrasting polar fringe<sup>13</sup>. On blue photographs taken on August 30 it was invisible<sup>10</sup>. At 21 h U.T. on August 31 the cap disappeared<sup>14</sup> and the region became covered by a yellowish fog. Sadil<sup>8</sup>, using a red filter, observed a remnant of the cap as an insignificant brilliant spot on the days following. At the same time, only small white spots appeared at the original location of the cap<sup>15</sup>. On September 7 the cap was again visible even without a filter; its dimensions increased, and on September 15 it had attained its normal appearance and brightness<sup>8,16</sup>.

The foregoing observations indicate that the cap, or at least a large part of it, really disappeared and was renewed in the first ten days of September. A similar opinion is held by Kuiper<sup>9</sup> and Dzhipiashvili<sup>16</sup>. It is indeed difficult to explain all the phenomena described as merely phenomena occurring in the atmosphere of Mars due to internal effects. The possible influence of the exceptionally strong solar activity after August 20 and the flare on August 31, 1956, greatly facilitates an explanation of these phenomena.

Flares giving an increase in cosmic radiation that can be recorded on the Earth's surface are very exceptional phenomena; flares accompanied by sub-cosmic (proton) radiation, however, occur more frequently. A flare of importance 3 on August 31, 1956, was observed at a number of astronomical observatories including that at Ondřejov: position 14° N., 14° E., commencement 12.26; phase Y—ejection 12.40; first cosmic particles on Earth ~12.46 and increase in cosmic radiation in maximum about 2 per cent<sup>4</sup>; range of relatively slower solar protons

according to effect of polar cap absorption of cosmic radio noise 14.30; the peak integral proton intensity with energy >10 MeV was 192 (cm<sup>2</sup> sec ster)<sup>-1</sup> according to Bailey<sup>17</sup>.

Since the cloud of cosmic and sub-cosmic particles from this flare still reached the Earth on August 31, Mars must necessarily have been hit in view of its suitable spatial location with respect to the Earth and Sun at the time of opposition. Moreover, it is seen<sup>18</sup> that streams of a cloud of particles are very extensive at a distance of 1 a.u. in space, so that the probability of hitting planets is large. The situation in the interplanetary space according to measurements of cosmic radiation at Mount Washington in August 1956 was such that already in the second and third thirds of August Forbush effects had occurred. Such effects indicate the existence of an extraordinary cloud of solar particles with magnetic field in the space around the Earth. From August 31 to September 1, 1956, after the increase in cosmic radiation, a far larger Forbush effect than the foregoing occurred. Thus from September 1 to about September 7 the interplanetary space in the direction towards the Earth and Mars must have been filled with very dense clouds of slow and very fast particles from important flares on the Sun.

Short-wave radiation in the period of the large flare on August 31, and particularly the ejection of particles having velocities in a range of 10,000–100,000 km sec<sup>-1</sup>, by penetrating deep enough into the atmosphere of Mars could cause photochemical and temperature changes of such extent that some of the aforementioned extraordinary processes in the atmosphere of Mars could occur at the end of August and beginning of September 1956. Apart from the already published hypotheses, we would explain the disappearance of the cap by the fact that during extraordinary X-emission from a flare, and particularly during the penetration of the particles, an increase in temperature occurred which led to the sublimation process of evaporation of crystals of which, it is deduced, the atmospheric part of the cap consists. The interval and duration of the disappearance of the cap, about 6 days, correspond to the interval and duration of a particularly intensive Forbush effect on records of cosmic radiation<sup>4</sup>.

## PHYSICS

## Domain Structures in Liquid Crystals, induced by Electric Fields

THE recent report by Williams<sup>1</sup> of domain structures in *p*-azoxyanisole appeared at a time when we were obtaining similar effects with related compounds in these laboratories. Until the appearance of Williams's report, there appears to have been nothing published on electric field effects since 1943 (ref. 2). In reviewing the contradictory theories of a number of workers, Gray<sup>3</sup> has concluded that the nature of the orientating effects of applied electric fields is not clear, and the directions in which the major axes of the molecules become orientated with respect to the field are uncertain. An extensive investigation is required to resolve the existing contradictions.

We have observed large domains in liquid crystals, differing somewhat in size and structure from those reported by Williams, and produced by smaller electric fields. The samples were melted between plates of electrically conductive glass, and were usually about 0.5 mm thick. The compounds examined were those exhibiting a nematic mesophase between certain temperature limits. Compounds differed widely in the patterns observed and in their response to d.c. and a.c. fields.

The first experiments were made with *N*-*p*-methoxybenzylidene-*p*-phenylazoaniline:

with a solid to nematic transition at 185°–186° C. The compound was held a few degrees above the transition temperature and an electric field applied from a potentiometer. With a d.c. field of between 100 and 200 V/cm

Fig. 1

Fig. 2

Fig. 3

a pattern of large parallel domains could be seen clearly by transmitted light with the naked eye, and was very prominent under a magnification of only four times. Fig. 1 shows the appearance of the sample at the optimum field strength of about 160 V/cm, and a magnification of 4. An enlarged view in Fig. 2, at a magnification of 25, shows the irregularities and reveals a nodular fine structure. Below a field strength of 100 V/cm, little ordered structure was observed, and above 200 V/cm the structure became finer and less well defined. At 600 V/cm all ordered structure had disappeared, giving a moving mass of small scintillating particles. No similar effects could be obtained with a.c. fields.

Comparative tests with *p*-azoxyanisole have shown that it behaves in a similar manner to that described by Williams, and gives a much finer domain structure, with no well-defined pattern visible to the naked eye.

In contrast, *p*-anisalazine:

with a transition point at 165° C, again exhibited the formation of macro-domains, which were thinner and smoother than those of *N*-*p*-methoxybenzylidene-*p*-phenylazonaniline. The optimum d.c. field strength for domain formation is about 100 V/cm, but a slightly clearer pattern is obtained from a 100-V/cm root mean square 50-c/s a.c. field. Both d.c. and a.c. fields had minimum critical values of about 70 V/cm, and the structure began to break up above 200 V/cm. Fig. 3 illustrates the structure obtained in a 100-V/cm a.c. field, at a magnification of 25 times. A curious feature is the 'pairing' effect of the lines.

The arrays of domains shown in the photographs contained units up to 5 mm long, with widths of 0.1–0.2 mm. The patterns closely resembled those obtained for domains in ferroelectric<sup>4</sup>, ferromagnetic<sup>5</sup> and ferrimagnetic materials<sup>6</sup>. The macro-domains took approximately 3 sec to form after applying the field and a similar period to disappear after switching off. While they were clearly visible by direct illumination, viewing between crossed 'Polaroids' increased the definition. Very clear patterns were also obtained in a Schlieren optical system.

It is clear that existing theories<sup>2</sup> are not adequate to explain the behaviour of mesomorphic materials in electric fields. A comprehensive theory must account for the following facts: (a) Compounds with similar structures, for example, *p*-azoxyanisole and *p*-anisalazine, give widely different types of domain pattern, at low field strengths in the region of 100 V/cm. (b) Closely related compounds, for example, *p*-anisalazine and *N*-*p*-methoxybenzylidene-*p*-

phenylazoaniline, behave differently in alternating fields, the former giving a well-defined macro-domain structure, but the latter remaining relatively unaffected. (c) The macro-domain structure, produced by low field strengths of 100–200 V/cm, breaks down completely for a small increase in the field to 500–600 V/cm, but not because of electrolysis or mass transport.

The foregoing observations were made in the course of a research programme on the switching of light beams by using small electric fields. The light transmission of a film of *N*-*p*-methoxybenzylidene-*p*-phenylazoaniline in the nematic phase showed large changes when fields were applied: a field of 2,000 V/cm decreased the transmission to about 35 per cent of its initial value. The effect was apparently produced by an increase in the light-scattering properties of the film. Under a field of 2,000 V/cm, the liquid displayed a mass of fast-moving scintillating particles.

We thank Standard Telecommunication Laboratories, Ltd., on whose behalf this work was carried out, for permission to publish it.

### Electrification of Porous Alumina on Desorption of Gases

ELECTRIFICATION of some dusts by friction, and, hence, the association of sandstorms with static electricity, are well known; laboratory work on the subject has been summarized in two publications dealing with the study of small particles<sup>1,2</sup>. Further work has shown<sup>3</sup> that particles of sodium chloride and, hence, dry sodium chloride aerosol, may, in some circumstances, acquire strong electric charges by emission of photoelectrons. We wish to report here yet another form of electrification of some small particles. This occurs when small particles desorb gas, and it would seem that both the magnitude and the sign of electrification are associated with the chemical treatment which was given to the substance during its preparation.

The present experiments were carried out on three types of Merck activated alumina (reagent purity, marketed for use in chromatography), which are available under the names of 'Alkaline', 'Neutral' and 'Acid' alumina. Although data on the exact procedure of preparing the three varieties have not yet been released for publication (Merck, personal communication), it can be assumed that amphoteric alumina is prepared so as to contain an excess of alkali (such as Na) or acid species, which it may exchange. Hence, 10 per cent aqueous suspensions of such alumina preparations reach, with time, pH values of 9.5, 7.0 and 4.5, in the case of 'Alkaline', 'Neutral' and 'Acid' products, respectively.

The products were desiccated in an electric oven, ground in an agate mortar to pass through a -270 Mesh (ASTM), and then separated into fairly uniform fractions by centrifuging<sup>4</sup> (see Fig. 1). Those fractions which had a specific surface area of about 180 m<sup>2</sup> × g<sup>-1</sup> (as measured by the Brunauer–Emmett–Teller method at low relative pressures of nitrogen) were later evacuated in suitable 'Pyrex' vessels at 250°C for at least 24 h. When the vacuum reached a value of less than 10<sup>-4</sup> torr, the fractions were adsorbed and compressed for 60 min to about 400 torr above atmospheric pressure, with pure

Fig. 1. Percentage particle-size, obtained by microscopy, of the three types of alumina used

nitrogen, oxygen, nitrous oxide, or dry laboratory air. This treatment appeared to make the particles electrically charged for prolonged periods of time, as revealed by tests using an electrometer, and this charge appeared to depend on the desorption of gas from the solid. Thus, in order to evaluate the effects obtained, a series of experiments was carried out using the technique described in ref. 3. Briefly, the method consisted of allowing a stream of monodisperse particles of known apparent density and size to trickle between charged plates. Calculations were made of both the initial charge and the rate of charging from the trajectory of the stream, which was photographed under suitable illumination.

It had been found earlier that the following equation held:

$$l_v = \frac{\epsilon^2 g^2}{108 E \mu \alpha} d^3 \frac{l_h}{l_v} - q_0 \frac{\epsilon g}{18 \pi \mu \alpha} \quad (1)$$

where:  $l_v$  was the vertical component, in centimetres, of the distance of fall, from the entry of particles into the electric field;  $l_h$ , the horizontal component;  $d$ , the diameter of particles (cm);  $\epsilon$ , the apparent density of particles, g × cm<sup>-3</sup>;  $g$ , the acceleration due to gravity, taken here as 980 cm.sec<sup>-2</sup>;  $\mu$ , the viscosity of the air, taken here as 185 × 10<sup>-6</sup> poise;  $E$ , the electrical field in c.g.s. units;  $q_0$ , the charge on particles before entry into electric field, in E.S.U.;  $\alpha$ , the rate of charging of particles during their fall, in E.S.U.sec<sup>-1</sup>cm<sup>-2</sup>.

Equation (1) makes it possible to estimate both  $q_0$  and  $\alpha$  from graphical plots of  $l_v$  versus  $l_v/l_h$ . We found that

Fig. 2. Example of plots, according to equation 1 of data obtained from 8 photographs per diagram, using alternately both polarities, and average results. Each plot represents a series of experiments carried out at different values of the electric field between charged plates at a distance of 8.0 cm, and with 'Neutral' alumina which was charged with nitrogen under pressure. All results obtained are summarized in Table 1;  $\alpha$  was computed from slopes and hence  $q_0$  from intercepts

charging the substance with nitrous oxide ensures a slow prolonged evolution of gas (as observed gravimetrically) and similarly, in the cases when nitrogen was used, reproducible results could be obtained; Fig. 2 illustrates an experimental plot obtained using nitrogen gas on 'Neutral' alumina, while Table 1 gives the results obtained using both nitrogen and nitrous oxide on all types of alumina. It can be seen that, while both the 'Alkaline' and 'Neutral' species of alumina show, during the period of time immediately following decompression, a strong tendency towards positive electrification, the acid particles reveal a very small negative electric effect which, although too small to be revealed by the method described, can be qualitatively detected by means of an electrometer.

Hanle *et al.* have recently observed a process of electrical charging of solids when water of crystallization evaporates from some salts<sup>5</sup>, and Mühleisen found polarity fluctuations of electrical charges on dusts, which depended on whether the particles adsorbed or desorbed water<sup>6</sup>. A similar occurrence, which appears to be associated with the desorption of gas, is observed here and may have some

Table 1. SUMMARY OF DATA ON ELECTRIFICATION OF ALUMINA UNDER DIFFERENT CONDITIONS

Alumina	Average diameter ( $\mu$ )	Computed density ( $\text{g cm}^{-3}$ )	Gas used for compression	Average $q_0$ (E.S.U.) $\times 10^8$	$\alpha$ (E.S.U. sec <sup>-1</sup> cm <sup>-2</sup> ) $\times 10^9$
'Alkaline'	21 $\pm$ 7	1.8 $\pm$ 1.0	N <sub>2</sub>	+1.6 $\pm$ 1.0	+2.4 $\pm$ 1.0
'Neutral'	25 $\pm$ 6	1.3 $\pm$ 0.7	N <sub>2</sub>	+3.8 $\pm$ 1.0	+1.4 $\pm$ 0.5
'Acid'	24 $\pm$ 6	1.6 $\pm$ 0.8	N <sub>2</sub>	Very small negative	/
'Alkaline'	21 $\pm$ 7	1.8 $\pm$ 1.0	N <sub>2</sub> O	-0.1 $\pm$ 0.5	+1.9 $\pm$ 0.7
'Neutral'	25 $\pm$ 6	1.3 $\pm$ 0.7	N <sub>2</sub> O	+0.7 $\pm$ 0.5	+1.5 $\pm$ 0.5
'Acid'	24 $\pm$ 6	1.6 $\pm$ 0.8	N <sub>2</sub> O	Very small negative	/

Apparent density of powders was computed on the basis of an average of 25 readings of times of fall of substances examined, in glass tube 150 cm long, 4 cm internal diameter, at 25° C.

bearing, in Nature, on certain problems related to atmospheric electricity. Electrification of this type may be expected to occur on certain types of particles when they are carried upwards into regions of lower atmospheric pressure; furthermore, depending on the nature of the soil, 'desorption' of electrical charges may be expected to occur in suitable atmospheric conditions (such as, for example, fluctuations of pressure), and to be one of the causes of the 'electrode effect' (see, for example, the recent paper by Crozier<sup>7</sup>).

### Single Bi-particle Elastic Collisions of Fast Protons with Metals

RECENT experiments<sup>1,2</sup> have shown that when metals are bombarded with energetic protons and ions, charged particles are emitted along with neutral particles. The present work was carried out to analyse the emitted ions and to establish that fast protons and molecular hydrogen ions make single bi-particle elastic collisions with atoms lying on a metal surface where they behave as if they are effectively isolated from the lattice.

The technique used to locate the emitted ions differed from conventional methods so far used in mass spectrometry. The ions were received on a metal collecting plate after traversing a sector magnetic field, and their position was determined by the visible light they emitted at the point of impact, where they caused metal electron plasma oscillation giving rise to soft electromagnetic radiation<sup>3</sup>.

The ion beam was obtained from a 30-Mc/s radio-frequency source and was accelerated in the Cockcroft-Walton apparatus at this Laboratory. Protons and hydrogen molecular ions, while passing through a fine canal, bored along the axis of a pure copper rod, 4 cm long and 1 cm diameter, struck atoms lying on its surface and transferred their energy and momentum to them. The maximum value of energy  $E_2$  and of momentum  $P_2$ , which are transferred in an elastic bi-particle collision by an incident ion of mass  $M_1$  to a target atom of mass  $M_2$ , are given by the equations:

$$E_2 = 4 \frac{M_1 M_2}{(M_1 + M_2)^2} \cdot E_1 \quad (1)$$

$$P_2 = 2 \frac{M_2}{(M_1 + M_2)} \cdot P_1 \quad (2)$$

where  $E_1$  and  $P_1$  are the energy and momentum respectively of the incident ions.

The ions emitted from the canal were confined by its geometry to a narrow pencil, almost parallel to incident protons, and possessed groups of particles of discrete energies. Along with the incident ion beam, they entered a brass chamber, 20  $\times$  15  $\times$  3 cm, placed about 3 cm below the canal, and described trajectories in the sector field the radii of curvature of which depended on their

charge and momentum. They fell on the metal wall of the chamber and emitted light at the points of impact; this could be observed through a glass plate which had been fixed on the opposite side of the chamber with soft 'Araldite'. The position of protons and hydrogen molecular ions was always well defined on the chamber wall, and their deflexion due to magnetic field, thus determined, agreed within probable error of measurements with our theoretical calculations.

The field of the electromagnet was calibrated with a Grassot's fluxmeter within the pole pieces and outside, extending to the copper canal and the side walls of the analyser. The chamber, together with the accelerating column, was evacuated by a fast oil pump backed by a Kinney pump through a 'Freon' cold trap, and the pressure inside it was kept as low as  $10^{-6}$  mm mercury during the experiments.

At an incident ion energy of 360 keV and with a suitable fixed magnetic field, well-defined spots could be seen on the metal wall of the analyser. These were due to singly and multiply charged copper ions, such as  $\text{Cu}^+$ ,  $\text{Cu}^{2+}$ ,  $\text{Cu}^{3+}$ ,  $\text{Cu}^{4+}$  and  $\text{Cu}^{5+}$ , which were emitted from the canal surface by fast protons and molecular hydrogen ions. The spots due to  $\text{Cu}^{2+}$  ions overlapped with those due to incident ions causing their emission, but all other spots were well separated from one another, indicating that there was no appreciable energy spread among the emitted ions belonging to a particular group and entering the analyser. The energy and momentum of these ions, as calculated from the deflexion they experienced in the magnetic field, were in agreement, within experimental error, with equations (1) and (2). Copper ions carrying more than five charges were not detected within the energy range of the incident ions investigated. At an energy of 100 keV of the incident ions there were three spots, at 200 keV five, while at 360 keV all the aforementioned species of charges appeared. This made us believe that the efficiency of emission of ions and the multiplicity of their charge rise with energy of the incident beam.

We were not able to detect any ions of impurities which, it was suspected, might be present in the discharge tube of the radiofrequency ion source, and hence we believe that all the emitted Cu ions were due to single bi-particle elastic collisions of protons and hydrogen molecular ions with Cu atoms lying on the surface of the canal. There is some uncertainty as to the nature of one or two rather faint spots which occurred in the momentum spectrum (which was spread over a length of 10–11 cm). The only plausible explanation that we can offer is that they were formed due to multiply charged ions the positive charge of which was degraded during their flight in the trajectories in the magnetic field from the canal to the collector plate. No attempt was made to detect whether complex particles<sup>3</sup>, for example of any compound of copper, were emitted in these experiments from copper surface. If they were, they overlapped with Cu ions.

The incident beam current on the copper canal and the thick metal disk which held it in position varied between 30 and 40  $\mu\text{amp}$ , while the energy of the incident ions ranged between 100 keV and 360 keV in these experiments.

We thank His Excellency Nawab Malik Amir Mohammed Khan, Governor of West Pakistan, for his encouragement to our research, and Sir John Cockcroft for his interest in these experiments.

## GEOFYSICS

### Role of Plasma Instabilities in Auroral Phenomena

RECENTLY it was proposed that plasma instabilities are responsible for the auroral precipitation of particle trapped inside the magnetosphere<sup>1</sup>. The entire event would be a two-step process, one which takes particle inside the magnetosphere and one which dumps the trapped particles. Responsible for the second step would be plasma micro-instabilities of the type outlined by Krall and Rosenbluth<sup>2</sup>.

Against this view is the fact that the number of particles and the amount of energy contained inside the radiation belts are barely sufficient to supply one auroral event<sup>3</sup>. Moreover, micro-instabilities are not the most suitable ones for explaining gross plasma motion and can be inhibited by a number of factors<sup>4</sup>, such as the presence of a shear in the magnetic field.

The necessity of overcoming these objections leads one to look for plasma macroscopic instabilities which exist in collisionless regimes and do not respect the constraint that particles move together with the lines of magnetic field. Instabilities of this nature may be suitable for explaining the first step, as they would allow potential energy stored in the magnetic field of the thermalized solar wind to be transferred into kinetic energy. This process could occur inside the magnetopause or on the corresponding nightside.

In order to avoid having to consider the trapping and dumping phase, it is proposed that the instability excites plasma waves and then accelerates particles according to a pattern of the type considered by Stix<sup>5</sup>.

Although at the present stage it is difficult to identify one definite type of plasma instability as being responsible for the auroral process, I would mention that two classes of macroscopic collisionless instabilities have been investigated<sup>6,7</sup>. One of them<sup>7</sup> is related to the appearance of an electric field parallel to the lines of the magnetic field, so that the 'frozen-in law' does not hold, due to anisotropic pressure and ion gyro radius effects. The driving factor is a spatial gradient of the longitudinal electron pressure or a gradient of the density together with transverse pressure gradients. In the case when the equilibrium magnetic field has no shear, the growth rate of this instability is of the order:

$$\gamma \approx k \frac{p_{e\parallel}}{\rho \Omega}$$

where  $k$  is the wave number transverse to the magnetic field,  $p_{e\parallel}$  the transverse gradient of the longitudinal electron pressure,  $\rho$  the mass density and  $\Omega$  the ion gyro frequency. Assuming typically that:  $p_{e\parallel}/\rho \approx v_{the}^2$ ,  $R \approx 10^9$  cm,  $v_{the} \approx 4 \times 10^7$  cm/sec,  $B \approx 10^{-3}$  gauss,  $k \approx 10^{-7}$  cm<sup>-1</sup>, we obtain  $\gamma \approx 10^{-1}$  sec<sup>-1</sup>. For shorter wavelengths, that is  $k \approx 10^{-6}$  cm<sup>-1</sup>, the growth time becomes  $10^{-1}$  sec, which seems to be consistent with the duration of burst of auroral X-rays observed recently<sup>8</sup>.

## GEOCHEMISTRY

Formation of Cobalt (III) in the Amorphous  $\text{FeOOH} \cdot n\text{H}_2\text{O}$  Phase of Manganese Nodules

RECENT discussions<sup>1</sup> on the nature of 3d transition-metal ions in sea water and in manganese nodules have rejected the possibility that oxidation of cobalt to Co (III) occurs in marine environments. A detailed electron microprobe study of manganese nodules<sup>2</sup> from diverse geographical localities supports the belief<sup>3</sup> that there is a cobalt-iron inter-element relationship in the nodules. Cobalt is enriched in the X-ray amorphous  $\text{FeOOH} \cdot n\text{H}_2\text{O}$  phase in those nodules which contain appreciable amounts of iron. The results indicate that Co (III) and Fe (III) constitute an 'isomorphous' pair in the amorphous  $(\text{Fe}, \text{Co})\text{OOH} \cdot n\text{H}_2\text{O}$  phase, which may be recrystallized to goethite on treatment with hydroxylamine hydrochloride.

Thermodynamic calculations support the hypothesis that  $\text{Co}^{2+}$  in sea water may be oxidized to  $\text{Co}(\text{OH})_3$  under certain conditions. The model on which the calculations are based is as follows:

Reaction:

$$\Delta G_{298}^0 = -52.53 \text{ k cal mole}^{-1} \text{ (ref. 4)}$$

$$\Delta S_{298}^0 = 60 \text{ cal deg mole}^{-1} \text{ (ref. 4)}$$

$$\Delta G_{275}^0 = -51.1 \text{ k cal mole}^{-1} \text{ (calc.)}$$

$$K = [(a_{\text{Co}^{2+}})^2 (a_{\text{OH}^{-}})^4 (a_{\text{O}_2})^{1/2}]^{-1}$$

Concentration of  $\text{Co}^{2+}$  in the Pacific Ocean<sup>5</sup>:  $0.38\text{--}0.67 \mu\text{g/l.}^{-1}$  or  $0.645\text{--}1.138 \times 10^{-8} \text{ m.}$

A typical depth for the formation of manganese nodules is 3,000 m (ref. 6)

pH of sea water at 3,000 m (ref. 7): 8.0;  $([\text{OH}^-] = 10^{-6} \text{ m})$

Temperature of the ocean at 3,000 m (ref. 7):  $2^\circ \text{C}$  ( $275^\circ \text{K}$ )

Average salinity of sea water at 3,000 m and  $2^\circ \text{C}$  (ref. 7): 35 g/1,000 g of sea water, corresponding to an ionic strength of approximately 0.6 m

Activity coefficient of  $\text{Co}^{2+}$  in a 0.6-M solution at  $2^\circ \text{C}$  (ref. 8): 0.49

Activity coefficient of  $\text{OH}^-$  in a 0.6-M solution at  $2^\circ \text{C}$  (ref. 8): 0.68

Partial pressure of oxygen at the sediment-water interface<sup>6</sup>: 0.25 atmosphere

Calculation: Taking  $[\text{Co}^{2+}]$  as  $10^{-8} \text{ m.}$

$$K = [(10^{-8} \times 0.49)^2 \times (10^{-6} \times 0.68)^4 \times (0.25)^{1/2}]^{-1} = 3.90 \times 10^{11}$$

$$\Delta G_{275} = \Delta G_{275}^0 + RT \log_e K = +1.24 \text{ k cal mole}^{-1}$$

Therefore, reaction (1) is unfavourable when the  $\text{Co}^{2+}$  ion concentration is  $10^{-8} \text{ M.}$  However, the reaction has a negative free energy when the  $\text{Co}^{2+}$  ion concentration exceeds  $1.3 \times 10^{-6} \text{ M}$  (Fig. 1). Furthermore, reaction (1), which is probably catalysed by  $\text{Fe}(\text{OH})_3$ , is favoured by  $\text{Co}(\text{OH})_3$  forming a solid solution with  $\text{Fe}(\text{OH})_3$ . Also, the reaction is more likely to proceed in oxidizing environments.

The question arises whether the  $\text{Co}^{2+}$  ion concentration in sea water ever exceeds  $1.3 \times 10^{-6} \text{ M.}$  The cobalt-rich manganese nodules are found on the floor of the central Pacific Ocean<sup>6</sup> in the neighbourhood of basaltic islands, atolls, and guyots. Most basalts have cobalt concentrations

Fig. 1. Variation of  $\Delta G_{275}$  with  $\text{Co}^{2+}$  ion concentration for the reaction:  $2 \text{Co}_{\text{aq}}^{2+} + 4 \text{OH}_{\text{aq}}^{-} + \frac{1}{2} \text{O}_{2(g)} + \text{H}_2\text{O} = 2 \text{Co}(\text{OH})_{3(s)}$ . Ranges of the  $[\text{Co}^{2+}]$  in sea water and basalt are indicated

between 30 and 80 p.p.m. (ref. 10) ( $0.5\text{--}1.4 \times 10^{-6} \text{ M}$ ). Therefore, submarine vulcanism with subsequent leaching of the basaltic glass or palagonite could raise the cobalt concentration of sea water above  $1.3 \times 10^{-6} \text{ M}$  locally. This would favour reaction (1), and account for the enrichment of cobalt in the amorphous  $(\text{Fe}, \text{Co})\text{OOH} \cdot n\text{H}_2\text{O}$  phase of manganese nodules. The low cobalt content in manganese nodules which formed in areas adjacent to the American continent<sup>6</sup> may be attributed to a lack of basaltic bed-rock and to the reducing environment in the sediments.

Several simplifications are inherent in the calculations here. In particular, the effect of pressure at depth on the reaction, the variation of the ionization constant of water with temperature, and the presence of dissolved cobalt in a form ( $\text{CoSO}_4$ ,  $\text{CoCl}_4^{2-}$ , etc.) other than the simple  $\text{Co}^{2+}$  ion have been ignored. Nevertheless, the calculations demonstrate that oxidation of cobalt to a hydrated cobaltic oxide is a feasible process in certain marine environments. Similar calculations for nickel indicate that oxidation of  $\text{Ni}^{2+}$  to  $\text{Ni}(\text{OH})_3$  is unlikely ( $\Delta G_{275} = +21 \text{ k cal mole}^{-1}$  when  $[\text{Ni}^{2+}] = 10^{-7} \text{ M}$ ).

This work was supported by scholarships from the Royal Commission for the Exhibition of 1851, London, and the University of California.

## METALLURGY

## Grain Size of Ausformed Steel

THE grain size of the ultra-strong, ausformed steels is probably an important factor in their strength and ductility, but it is yet uncertain. The structures are so fine and complex that even the electron microscope has not hitherto revealed the grain structure clearly. However, a flexible dark field technique described previously, using the EM6 electron microscope, has been found to reveal it satisfactorily<sup>1</sup>.

Fig. 1 shows the structure, as seen under ordinary light-field conditions, of an ausformed steel, details of which are given below. The appearance can be varied a good deal by tilting the specimen, but there is usually uncertainty, as in Fig. 1, where one grain ends and another begins. Fig. 2 shows the diffraction pattern from this area; the great number of spots produced by the tiny area ( $\sim 10\mu^2$ ) bathed by the electron beam immediately makes it clear that the separate reflecting units are minute. That part of the pattern which is covered by a circular half-tone patch was aligned along the microscope axis, the objective aperture placed in position, and Fig. 2 was obtained; the patch is the objective aperture.

Fig. 1. Ausformed steel. Light-field electron micrograph ( $\times 27,000$ )

Fig. 2. Diffraction pattern of the area shown in Fig. 1

Fig. 3. Same area as shown in Fig. 1, dark-field illumination ( $\times 27,000$ )

Fig. 4. Another area, dark field ( $\times 140,000$ )

With the illumination so adjusted, Fig. 3 was then photographed. Fig. 3 is therefore the dark-field counterpart of Fig. 1. In Fig. 3 there are bright areas in a generally dark ground. The bright areas are, of course, the regions which diffract the beams selected in Fig. 2. They can be seen in Fig. 3 to be contained for the most part in a few irregularly-shaped regions or grains which are patchily illuminated. If the specimen was now tilted, a bright area would typically migrate across the grain containing it during a tilt of a few degrees and then disappear, and a new bright area might flash up elsewhere beginning to outline another grain. The irregularly-shaped regions are therefore warped grains of which the ausformed steel appears to be composed. The majority had sizes of 1000–2000 Å, although some seemed to be as small as 100 Å. They are thus very small, as the diffraction pattern had suggested.

Because the illumination in the dark field condition is accurately axial in the microscope, full resolution is available. Fig. 4 is of a bright area magnified  $\times 140,000$  and shows it to contain very many dislocations indeed.

The majority of grains of the same steel in the plain martensitic condition (see below), when examined in the same way, proved to have sizes of between 2000 and 5000 Å.

The yield strength of a steel is known to be related to its grain diameter  $d$  by the Hall-Petch relationship  $\sigma_y = \sigma_i + k_y d^{-1/2}$ , where  $\sigma_i$  represents the resistance to the motion of a dislocation through the metal and  $k_y$  is a constant having a value of about 2 kg/mm<sup>2</sup>.mm<sup>1/2</sup>. Taking the average grain sizes of the ausformed and martensitic samples as 1500 and 3500 Å respectively, the superiority of the ausformed steel so assessed should be 53 kg/mm<sup>2</sup>, which compares quite well with the actual difference of 45 kg/mm<sup>2</sup> (ref. 3). Petch<sup>2</sup> has derived a relation between the tough brittle transition temperature of a steel and its grain size. According to this the ausformed material should have a transition temperature 20°–30° C lower than that of the martensitic. The actual transition temperature of the materials has not yet been determined but, as would be expected from this difference, the ausformed condition is appreciably the more ductile at room temperature, showing a reduction of area of 25 per cent against only 4 per cent for the martensitic.

With the flexible dark-field technique it is therefore possible to investigate the grain structure of ausformed steel. A thorough examination is needed before really firm conclusions can be drawn. However, so far as these results go, in the particular material examined much of the improved strength and ductility caused by ausforming is due to extra-fine grain size.

The samples of steel, and information about them, were made available by Mr. W. E. Duckworth, Dr. Irani and Mr. P. Taylor of the British Iron and Steel Research Association. The steel, which contained 13 per cent Cr and 0.3 per cent C, was austenitized at 980° C. To produce the ausformed condition it had been quenched at 500° C, rolled to 50 per cent reduction at that temperature, and air cooled to room temperature. Its tensile strength and reduction of area at room temperature were 235 kg/mm<sup>2</sup> and 25 per cent, respectively<sup>3</sup>. To produce the martensitic condition it had been water-quenched to room temperature. Its strength and reduction of area were then 90 kg/mm<sup>2</sup> and 4 per cent, respectively<sup>3</sup>.

## MINERALOGY

### Mass Spectrometric Analysis of the Gas evolved from Some Heated Natural Minerals

It has been known since the late nineteenth century that rocks and minerals evolve gas when heated. Early workers<sup>1,2</sup> were hampered by the lack of adequate methods for analysing small quantities of gas. They attempted to offset this by using large samples, so that their investigations were mainly restricted to whole rocks<sup>3</sup>. The use of modern physical methods has made possible the accurate analysis of small amounts of gas<sup>4</sup> (< 0.1 cm<sup>3</sup> S.T.P.), and a method has been developed for using an A.E.I. MS 10 mass spectrometer to analyse the gas evolved by heated minerals.

Half-gram samples of separated minerals were heated at temperatures up to 1,100° C in a quartz tube attached by a quartz-'Pyrex' graded seal to a grease-free, 'Pyrex' high vacuum system. As the gas was evolved, it was moved by an automatic Toepler pump into a reservoir where water and carbon dioxide were condensed in a trap cooled with liquid air. A known amount of neon was added to the remaining non-condensable gases as an internal

standard. The mixture was analysed using the mass spectrometer which had been calibrated with pure gases and known synthetic mixtures. At the conclusion of the mass spectrometric analysis the non-condensable gases were pumped away and the gas reservoir isolated. The cold trap was brought up to room temperature and the pressure, due to carbon dioxide and water, measured on an oil manometer. The contribution from carbon dioxide was measured after cooling the trap with solid carbon dioxide, and the water content found by difference. Since the reservoir volume had been calibrated, the amounts of the two gases could be found. The mass spectrometer was used to examine the gas from the Shap Fell and Skaergaard minerals for sulphur compounds as well as the gases shown in Table 1. Hydrogen sulphide and sulphur dioxide were found in the gas from the biotite but not in that from the other minerals.

The duplicate determinations give some indication of the reproducibility of results. In comparing analyses it should be remembered that an error which gives a low value for water results in too high a value for carbon dioxide, and that the results for carbon monoxide are less reliable than those for other gases (see footnote to Table 1). More than four months elapsed between the two analyses for plagioclase EG-5052 and the determinations involved different mass spectrometer operating conditions and calibration data. With the exception of methane the agreement is adequate.

The compositions of the gases evolved by the cogenetic minerals from Sierra Leone are remarkably similar even though the amounts differ by a factor of two. This suggests that the gas composition is independent of crystal structure and chemical composition of the host mineral. It is not possible to compare directly the cogenetic orthoclase and biotite from the Shap granite because of the presence of structural water in the mica.

Plagioclases EG-5052, EG-5181 and EG-4312 from the Skaergaard layered intrusion were taken from heights of 825, 1,800 and 1,925 m respectively (measured upwards from the lowest exposed layer<sup>5</sup>). They show a trend of increasing gas content with height (that is, with progressing crystallization). This late-stage concentration of volatiles is evident petrologically in the late formation of hornblende.

Pyroxene 722X487 gave four times as much gas as the other pyroxenes and plagioclases. It is also anomalous in containing more argon than could be produced by the decay of its potassium content<sup>6,7</sup>.

It is probable that at the time of mineral formation the volatiles were in equilibrium at the prevailing temperature and pressure<sup>8</sup>. If they were trapped in fluid inclusions, reactions would have occurred to maintain equilibria as conditions changed due to cooling, but since the kinetics become increasingly less favourable as temperature falls the final composition would correspond to equilibrium at a temperature above room temperature. This process would be reversed when the mineral was heated, until at about the temperature of formation the inclusions would break open<sup>9</sup> and release the volatiles into low-pressure conditions where reaction would continue in an attempt to reach equilibrium. It is unlikely that equilibrium was reached in the experimental arrangement described here, so that the measured gas composition represents an apparent equilibrium at a temperature and pressure between those prevailing at the time of mineral formation and those in the apparatus.

From the results in Table 1 it is possible to consider two independent equilibria:

$$Q = \frac{(V_{\text{H}_2}/V_T)(V_{\text{CO}_2}/V_T)}{(V_{\text{H}_2\text{O}}/V_T)(V_{\text{CO}}/V_T)} = \frac{V_{\text{H}_2} \cdot V_{\text{CO}_2}}{V_{\text{H}_2\text{O}} \cdot V_{\text{CO}}}$$

Tr = trace. N.D. = not determined.

\* During the mass spectrometric determination the ratio (amount of gas)/(amount of neon internal standard) changes due to fractionation. The carbon monoxide peak took a long time to stabilize and the initial ratio was calculated from the fall off in neon peak height using a factor of  $\sqrt{(20/28)}$  and not found by graphical extrapolation as for the other gases.

$$\Delta F^0 = -47,070 + 16.73T \log T + 3.12T \quad (2)$$

$$Q = \frac{(V_{\text{H}_2\text{O}}/V_T)P(V_{\text{CH}_4}/V_T)P}{(V_{\text{H}_2}/V_T)^3 P^3 (V_{\text{CO}}/V_T)P} = \frac{V_{\text{H}_2\text{O}} \cdot V_{\text{CH}_4}}{V_{\text{H}_2}^3 \cdot V_{\text{CO}}} \cdot \frac{V_T^4}{P^2}$$

where  $V_N$  is the volume of gas  $N$  and  $V_T$  is the total volume of gas measured at the same pressure as  $V_N$ ;  $P$  is the pressure;  $\Delta F^0$  is the change in standard free energy (data from Kubaschewski and Evans<sup>10</sup>), and  $Q$  is the proper quotient<sup>11</sup> becoming the equilibrium constant,  $K_p$ , when the reaction is at equilibrium. Equation (1) is independent of pressure and can be used to find the temperature of apparent equilibrium by comparing the experimentally determined value of  $Q$  with  $K_p$  calculated from free-energy data using the relationship  $\ln K_p = -\Delta F^0/RT$ . The values obtained are given in Table 1. If pressure is the only other unknown, then the value can be calculated from equation (2) using the value of  $T$  found from equation (1). For the Shap orthoclase this gives  $2.9 \times 10^4$  atm. at  $601^\circ\text{C}$  and  $6.7 \times 10^2$  atm. at  $975^\circ\text{C}$ . At the higher temperature reaction occurs more rapidly, so the apparent equilibrium pressure approaches more closely the pressure in the vacuum system. For the other minerals the calculated pressures vary from 0.3 atm. for pyroxene 722X487 to  $6.0 \times 10^4$  atm. for plagioclase EG-5052. This very large range, together with the fact that the temperatures calculated from equation (1) are greater than either the temperature of formation of the mineral or the heating temperature for most of the determinations, indicates that, if the measured amounts of gas are correct, then a simple two-variable model is inadequate.

It is possible that a high percentage of the evolved volatiles comes from secondary inclusions formed below the critical temperature of water, and still containing liquid water when they break open. The liquid will not be involved directly in gas phase reactions in the inclusions but will be included in the water measured by the method described here. Since only the amount of water in the gas phase should be used in calculating  $K_p$ , the value actually used is too high, and results in a high value for  $T$  calculated from equation (1), and a low value for  $T$  calculated from equation (2) at any given pressure. The high percentage of carbon dioxide from pyroxene 722X487 and plagioclase EG-5181 and the low apparent equilibrium temperatures suggest that carbon dioxide in excess of that present in the gas phase of the inclusions has been included in the total measured. This could have come from carbon dioxide dissolved in the aqueous phase, a separate carbon dioxide phase or from the decomposition of carbonates.

Investigations are being continued on minerals with observable fluid inclusions (quartz, fluorite, etc.) using

lower heating temperatures to minimize chemical reactions: eventually it is hoped to crush minerals in vacuum.

I thank Prof. L. R. Wager, Dr. N. J. Snelling and Dr. C. R. Evans for supplying separated minerals, and I acknowledge an Oxford University Burdett-Coutts studentship.

## CHEMISTRY

### Measurement of Adsorption Isotherms by a Gas Chromatographic Technique

RECENT developments in the field of gas chromatography have included the measurement of gas-solid adsorption isotherms from the retention data<sup>1-3</sup>. A peak obtained from a single injection is used to calculate a series of retention volumes, ranging from the highest partial pressure at the peak maximum to zero partial pressure where the diffuse edge coincides with the baseline. These retention volumes are plotted against the corresponding values of partial pressure, also obtained from the chromatographic peak, to give the first derivative of the adsorption isotherm as described by Cremer and Huber<sup>1</sup>. The isotherm is obtained from it by graphical integration.

Not all workers in this field have taken into account the lateral spreading of the chromatographic peak that occurs by the process of longitudinal diffusion of the particular material within the carrier gas stream. The easiest way of correcting for this term is that of Bechtold<sup>4</sup> who used a measure of the non-diffuse edge of the peak as a correction to the diffuse edge from which the isotherm was obtained. A correction was also applied by Owens, Hamlin and Phillips<sup>5</sup>, using measurements from a second peak obtained from a chemically similar species that was not physically adsorbed on the substrate. A

Fig. 1. Superimposed chromatograms. The numbers indicate the volume ( $\mu\text{l.}$ ) of water added

Fig. 2. Water adsorption isotherms of cleveandite: 1, using a single 0.6  $\mu\text{l.}$  water injection; 2, using a single 0.3  $\mu\text{l.}$  injection; 3, by frontal analysis; 4, using the 'peak maxima' method

the extent of longitudinal diffusion depends on the retention volume, this method of correction should require the adsorbed and the non-adsorbed species to have similar retention volumes.

As noted from the chromatographic peaks reported by most workers in this field<sup>2,6</sup>, the retention volumes of the diffuse edges are generally independent of the amount of adsorbate added, and in these cases the isotherm can be calculated from a single injection.

In obtaining water adsorption isotherms on silicate materials, we have, however, observed that the diffuse edge of the chromatographic peak changes from the leading to the trailing edge at a partial pressure of about 8 mm. This type of behaviour was previously observed by Glueckauf<sup>6</sup>, who suggested that the calculation of the isotherm should be split into two parts, corresponding to the leading and trailing parts of the diffuse edge. As the retention volumes of the diffuse edge when trailing are dependent on the amount of adsorbate added, a different isotherm will be obtained for each size of sample injection. This can be seen from Fig. 1, in which chromatograms obtained by adding varying amounts of water to cleveandite have been superimposed. It will be noted that the diffuse edges coincide when leading, but not when trailing.

Because of the difficulty of deciding which trailing-diffuse edge to accept, we have determined our isotherms

from a series of injections, taking measurements at peak maxima only and determining the retention volume for zero partial pressure by extrapolation of the curve drawn through the maxima of the superimposed peaks. The isotherm derived is shown in Fig. 2 together with one obtained by a frontal technique similar to that used by James and Phillips<sup>7</sup> and two isotherms calculated from single injections. It will be seen that a whole series of isotherms can be obtained using single injection methods. These are limited by the isotherm obtained by the peak maxima method, which itself shows good agreement with the isotherm obtained using the frontal technique.

Further work, involving the determination of isotherms of sulphur dioxide adsorption on charcoal, showed that in this case also the diffuse edges were dependent on the amount of adsorbate<sup>8</sup>, again indicating that the slope of the isotherm would vary according to the amount added, and that a 'peak maxima method' should be used in preference to a 'single injection' procedure.

### 'Stereo-chromatography': a New Method for Chemical Identification and Preparative Isolation

SINCE the initial reports on chromatographic techniques<sup>1</sup>, and more especially after the investigations of Consden, Gordon, and Martin<sup>2</sup>, and Martin and Synge<sup>3</sup>, numerous modifications of these procedures have made possible remarkable advances in biochemical research. By evaluation of migration characteristics of unidentifiable with identifiable solutes separated by partition chromatography, identification of unknown solutes has been made possible. Similarly, by utilizing preparative 'filter paper pile' techniques, such as the chromatopile<sup>4,5</sup>, the chromatopack<sup>6</sup>, or the chromatoblock<sup>7</sup>, constituents of concentrated mixtures can be chemically resolved to yield semi-micro-quantities of pure materials. The present communication concerns the feasibility of utilizing three-dimensional, compressed, paper-pulp blocks for preparative chemical isolation and identification. This technique has three distinct advantages: (1) It makes possible the analysis of an additional parameter, the 'spreading factor' ( $R_s$ ), which can be used to differentiate chemically constituents of the solute mixture together with conventional  $R_F$  values; (2) it offers a support system capable of handling and separating exceptionally concentrated loads of solute mixtures for subsequent semi-micro-determinations; (3) it provides a closed system which should inhibit oxidations or photochemical alterations of solute zones which sometimes occur in conventional paper chromatography. One disadvantage of the technique is that it requires a solid, compressed fibre block, which, although inexpensive to fabricate, is not yet commercially available. In addition, the procedure necessitates the use of an electric band or jigsaw for serial sectioning of the chromatographic block.

Preliminary chromatographic experiments were undertaken with compressed paper-pulp blocks (purchased from the Container Corporation of America, Santa Clara, California). The blocks were fabricated by compressing raw, 3-4 per cent, paper pulp at 3,000 lb./in.<sup>2</sup> in a metal sieve box by means of a Dake hydraulic press. After compression, which removed most of the water, the blocks were oven dried for 36 h at 70° C. It was found in previous compression experiments that homogenization of the crude paper pulp in a Waring blender before compression increased the homogeneity of chromatographic blocks.

The feasibility of stereo-chromatography was demonstrated by the three-dimensional separation of indicator dyes in simple ascending chromatography. According to the procedure of Porter<sup>6</sup>, indicator dyes were used as solutes in the organic phase of an equilibrated two-phase solvent mixture obtained by mixing 40 parts of 1-butanol, 10 parts of absolute ethyl alcohol, and 50 parts of water. This mixture was separated in a separatory funnel and the hyperphase was used.

In one early exploratory experiment, 1.5 ml. of an aqueous solute mixture containing 1.5 mg bromocresol green, 1.2 mg bromthymol blue, and 1.0 mg eosin blue was injected into the centre of the base of a 25 cm × 20 cm × 7.5 cm compressed pulp block. The block was placed on the bottom of a large, closed jar containing 0.5 in. of solvent mixture and exposed for 3 h, or until the solvent front almost reached the top of the block.

At the termination of the experiment, the block was removed from the solvent and serially sectioned by an electric band saw into 0.5 cm sections. Since the block cannot be readily dried internally, it is necessary to section wet blocks in order to prevent solute zone migration which might occur during prolonged drying.

Table 1. VERTICAL AND LATERAL MIGRATION IN STEREO-CHROMATOGRAPHIC BLOCKS

Solute	$R_F$	$R_S$
Methyl orange	0.32	0.08
Methyl red	0.68	0.24
Bromthymol blue	0.79	0.35
Methylene blue	0.88	0.04
Eosin blue	0.01	0.04

After the stereo-chromatogram was sectioned, the vertical and lateral migrations of the solute zones were determined on each section by means of a metric calibrated, transparent, plastic grid. The vertical migration ( $R_F$ ) values were determined in the conventional manner. The lateral migration, or spreading factor, of the solute zones was determined by calculating the ratio of the lateral spread of the solute from the central axis of the block to the vertical migration of the solvent front.

It was observed in most stereo-chromatographic blocks that zone resolution was adequate to isolate and identify the specific indicator dyes utilized. Of greater significance, however, is the fact that differences in lateral spreading ( $R_S$  values) of the indicator dyes were observed as shown in Table 1, which includes data from four recent experiments.

The present preliminary experiments indicate that stereo-chromatography with compressed paper-pulp blocks offers a suitable technique for preparative chromatography where large amounts of solutes are to be resolved. This procedure should therefore prove useful in biological, and possibly industrial, purifications.

Although additional experiments are necessary to evaluate critically the relation of  $R_S$  to  $R_F$  values, it is noteworthy that the spreading factor,  $R_S$ , offers an additional parameter for differentiating chemical constituents. Such a parameter should be of practical importance in differentiating compounds which have similar partition coefficients, and thus produce similar  $R_F$  values (for example, leucine and isoleucine, valine and *nor*-valine), but which differ in carbon chain configura-

tion. In conventional partition chromatography, Fisher and his associates<sup>8</sup> experimentally demonstrated that a linear relation holds between the area of the spot of a test substance and the logarithm of its original concentration. Brimley<sup>9</sup> has theoretically discussed this relationship by applying equations analogous to those developed in the theory of heat flow, and by assuming that the spot moves along the paper chromatogram (conventional chromatography) by simple diffusion. However, it would seem from the present preliminary stereo-chromatograms that such a simple relationship does not apply, analogously, to the volume of solute zones and their original concentration. It appears that the greater differences in  $R_S$  than in  $R_F$  migrations for a given solute pair (bromthymol blue and methylene blue) may indicate that lateral vectorial forces which influence solute zone movement (for example, solubility and/or ordinary diffusion, eddy diffusion, and local non-equilibrium) become more apparent in horizontal spreading than in vertical migration. In the latter case the capillarity and opposing gravitational forces are predominant. In other instances lateral, diffusive forces appear less predominant (methylene blue and eosin blue).

As in all chromatographic techniques, homogeneity of the supporting medium is necessary for regular movement of solvent and solutes. The blocks in the present experiments were fairly homogeneous, but less so than ordinary commercial filter paper. Fibre size can be expected to influence solvent flow rate in stereo-chromatography as it does in paper chromatography. Similarly, the initial flow rate (first 20 min) was found to be faster than in later periods in stereo-chromatography, as it is in conventional chromatography.

## An Oil-Wax-Surfactant System for retarding the Evaporation of Water

As a result of the growing use of fresh-water resources, much work has been done on retarding evaporation from water-storage facilities. Most of this work has centred about the use of a monolayer system, especially of long-chain fatty alcohols<sup>1</sup>. However, since the practical applications of the monolayer system show that amounts of material far in excess of the theoretical monolayer system must be used<sup>2</sup>, it becomes pertinent to examine other possible systems. It appears, however, that relatively little recent work has been done with possible systems other than the monolayer. Most investigations have been concerned with oil-surfactant systems<sup>3</sup> and one with a wax-oil system<sup>4</sup>.

I wish to report that I have found that certain petroleum oil-petroleum wax-surfactant layers are effective in retarding the evaporation of water. Some of the results are shown in Table 1. Many of these results, which were obtained on relatively small evaporation pans (about 1 sq. ft. in area), have been repeated using larger 10-ft. diameter pools with similar results. Preliminary information on testing with larger areas of water is also encouraging.

Table 1. RETARDATION OF WATER EVAPORATION BY VARIOUS SYSTEMS

Treatment	Amount of treatment* (g)	% Retardation efficiency† after 13 days outdoor exposure	% Retardation efficiency† after 20 days outdoor exposure
Long-chain fatty alcohol ‡	0.1	59.0	34.4
Oil-surfactant§	0.1	38.5	25.4

‡ Archer Daniels Midland's 'Adol 54' (commercial mixture of mainly *n*-hexadecanol and *n*-octadecanol) was used in isopropyl alcohol solution.

§ Applied in a hexane solution.

An oil-wax-surfactant system may have some advantages over a fatty alcohol system. Such systems float more easily, re-form more easily on disturbance, are biologically more inactive, less expensive, etc. However, many important problems remain to be investigated.

I am now investigating the system more closely in an attempt to gain control of the important variables. I am also co-operating with other interested groups in evaluating the practical possibilities of such a system.

### Solubility of Polyethylene Terephthalate

It is generally considered that polyethylene terephthalate is soluble only in a restricted range of rather specialized organic liquids, such as *o*-chlorophenol, tetrachlorethane/phenol, etc. It is the purpose of this report to describe conditions under which this range may be extended.

In the course of investigations into the mechanism and kinetics of the liquid-induced crystallization of amorphous polymer it has been postulated that crystallization occurs on a progressive front accompanying the diffusion of the particular liquid<sup>1</sup>. It was further considered that if this was by a two-stage process involving first of all solubilization and then crystallization it might be possible to isolate the first of the stages by correct choice of experimental conditions. Subsequent experimental verification of this view was obtained with chloroform and *sym*-tetrachlorethane separately using samples of amorphous film (8 × 10<sup>-3</sup> cm thick) in the two liquids at approximately -40° C. On standing overnight a precipitate formed, which on evacuation of liquid compacted to a hard solid of density 1.42 g/c.c. crystalline when submitted to X-ray diffraction analysis.

Since the polymer is apparently insoluble in these liquids at room temperature, it would suggest that any solubilization which occurs is immediately followed by crystallization. It is interesting to note that in the case of the *sym*-tetrachlorethane at room temperature, splitting of the film takes place. This supports to some

degree a previous contention that in thin films phase separation may arise in the middle of the crystallized material<sup>2</sup>.

That a similar phenomenon of solution and crystallization may be associated with other amorphous but crystallizable polymers is suggested by similar results on isotactic polystyrene<sup>3</sup>.

We thank Mr. P. Blakey for assistance in X-ray diffraction aspects of this work.

### Temperature Dependence of Contact Angles

THERE are very few recorded observations on the temperature coefficient of contact angles<sup>1</sup>. These suggest that the coefficient is very small, if not zero, which is at first sight surprising. Adam<sup>2</sup> has pointed out that, as a consequence, "it appears that temperature affects the surface tension and the adhesion to the solid to very nearly the same proportionate extent". He has discussed this in terms of the thermal motions of the liquid, and has suggested that "the decrease in the adhesive field of force with rising temperature is much less in solids than in liquids and is due principally or wholly to translatory motion". The implication, however, that the temperature coefficient of the free surface energy of solids is negligible because translatory motions are absent seems to require further justification.

It may be of importance to note that water was present as a liquid phase in all the cases cited by Elliott and Riddiford<sup>1</sup>, and by Adam<sup>2</sup>, since Neumann<sup>3</sup> has recently reported an appreciable decrease in the contact angles for several organic liquids against their saturated vapours, on a siliconed surface, when the temperature is raised from 12° to 28° C. Zisman<sup>4</sup> has argued that since the surface tension of a liquid decreases with rising temperature, the contact angle,  $\theta$ , should also decrease, but, as with Adam's suggestion<sup>2</sup>, this view appears to require the assumption that the temperature coefficient of the free surface energy of the solid is negligible.

The matter is one of both theoretical and practical importance. Consider Young's equation for a liquid against its saturated vapour on a solid surface:

$$\gamma_L \cos \theta = \gamma_s - \gamma_{SL} - \pi \quad (1)$$

where  $\gamma_L$ ,  $\gamma_s$  and  $\gamma_{SL}$ , respectively, are the free surface energies of the liquid, of the film-free solid and of the solid/liquid interface,  $\pi$  being the equilibrium film pressure. It is clear that the theoretical calculation of  $d \cos \theta / dT$  would require knowledge of the individual free surface energies and of their temperature coefficients.

Some progress has been made. Fowkes<sup>5</sup>, for example, has shown that internally consistent calculations of interfacial free surface energies can be made on the assumption that the energy of interaction between two phases is purely dispersive. On this valuable line of approach:

$$\gamma_{SL} = \gamma_s + \gamma_L - 2(\gamma_s^d \cdot \gamma_L^d)^{1/2} \quad (2)$$

where  $\gamma_s^d$  and  $\gamma_L^d$ , respectively, are the dispersive components of  $\gamma_s$  and  $\gamma_L$  (ref. 6) and equations (1) and (2) permit the evaluation of  $\gamma_s^d$  from contact angle measurements for cases in which  $\pi = 0$ . In certain cases,  $\gamma_s^d$  can also be evaluated when  $\pi$  is finite, and an estimate of

the temperature coefficients of  $\gamma_s^d$  and  $\gamma_L^d$  can be made<sup>7</sup>. In general, however, our lack of knowledge of  $\pi$ , and of its temperature coefficient, is a serious bar to further progress.

From equations (1) and (2):

$$\frac{d \cos \theta}{dT} = \frac{d}{dT} \left\{ \frac{2(\gamma_s^d \cdot \gamma_L^d)^{\frac{1}{2}}}{\gamma_L} \right\} - \frac{d}{dT} \left( \frac{\pi}{\gamma_L} \right)$$

$$= \frac{d}{dT} \left( \frac{W_{SL}}{\gamma_L} \right) - \frac{d}{dT} \left( \frac{\pi}{\gamma_L} \right)$$

where  $W_{SL}$  is the work of adhesion to the film-free solid, and the available data suggest that  $d(W_{SL}/\gamma_L)/dT$  is very small, at least for low-energy surfaces. On this view,  $d \cos \theta/dT \sim 0$  when  $\pi \sim 0$ . With one possible exception, the reported investigations for systems involving water are consistent with this conclusion. The possible exception is the unqualified statement by Fowkes and Harkins<sup>8</sup> that  $\theta$  has the same temperature coefficient of  $+0.06^\circ$  per degree centigrade for water both on paraffin wax and on graphite. In the first case  $\pi = 0$ , whereas there is an appreciable film pressure in the water/graphite system. It seems probable that their temperature coefficient for water on paraffin wax is too large, however, and is of the wrong sign<sup>7</sup>; the sign also seems wrong in the case of graphite. On the other hand, Neumann's results<sup>9</sup> are consistent with the present view since there can be little doubt that appreciable film pressures are present in his systems<sup>7</sup>.

On the practical side, we have made measurements using the sliding-drop technique<sup>9</sup> in order to augment the recorded investigations. These are summarized in Table 1, each value shown being the mean obtained from at least ten, and sometimes twenty, separate experiments. The scatter was less than  $\pm 2^\circ$  for the single liquid systems, the contact angle being much less reproducible for the two liquid system ( $\pm 7^\circ$ ).

†  $\pm 0.5^\circ$  in all cases.

‡ A light fraction paraffin oil.

In the cases of pure water and aqueous 2 molal sodium chloride, it will be seen that both  $\theta_A$  and  $\theta_R$  are sensibly independent of temperature, within the limits of experimental error. In the first case,  $\theta_A$  may be regarded as the equilibrium angle for the unpenetrated surface<sup>1,10,11</sup>, whereas  $\theta_R$  reflects the effect of penetration of water into the silicone layer<sup>11</sup>. The 2 molal sodium chloride system is evidently similar in the case of an advancing interface; the solute is negatively adsorbed at the solid/liquid and liquid/vapour interfaces, this having a small effect on  $\gamma_L$  and no discernible effect on  $\theta_A$ . On the other hand, the reduction in  $\theta_R$  as compared with pure water presumably indicates that penetration of water into the surface layer is increased by the presence of sodium chloride.

The other two systems present more difficulties. *n*-Butyric acid is positively adsorbed at both the solid/liquid and liquid/vapour interfaces; moreover, it may also adsorb at the solid/vapour interface, with the appearance

of a film pressure. The two liquid system is very different. Both the advancing and the receding cases involve, among other factors, the effect of temperature on the mutual solubility.

These results will be discussed in detail when further penetration investigations have been completed, but they serve to show that the temperature coefficient of  $\theta$  is not negligibly small for all systems. Moreover, quantitative consideration of the advancing results for pure water confirms the view that when  $\pi \sim 0$ ,  $d \cos \theta/dT \sim 0$ . Estimates of the temperature coefficients of  $\gamma_s$  ( $=\gamma_s^d$ ) and  $\gamma_L^d$  show<sup>7</sup> that  $d(W_{SL}/\gamma_L)/dT \sim 0$ . Now at 20° C,  $\gamma_L^d = 21.8$  ergs cm<sup>-2</sup> for water<sup>5</sup>, and  $\gamma_s \sim 33$  ergs cm<sup>-2</sup> for the silicone surface, both values being independent of investigations of contact angle<sup>7</sup>. Since  $\gamma_L = 72.8$  ergs cm<sup>-2</sup> at this temperature, we calculate  $\theta = 105^\circ$  from equations (1) and (2) on the assumption that  $\pi = 0$ . The agreement between this value and  $\theta_A$  for 22° C is at least a strong indication that  $\pi$  is very small at this temperature. The experimental values then suggest that  $\pi$  is negligibly small over the whole range 4°–75° C.

We thank the Iraq Petroleum Co., Ltd., for continuing financial support of these investigations.

## BIOCHEMISTRY

### Biological Activity of Retinoic Acid Ester in the Domestic Fowl: Production of Vitamin A Deficiency in the Early Chick Embryo

RETINOIC acid (vitamin A acid) is unable to replace retinol (vitamin A alcohol) in reproduction and vision in rats fed a vitamin A-deficient diet<sup>1,2</sup>. Results of similar tests with retinoic acid in poultry are presented in this communication.

Day-old chicks of both sexes were fed a retinol-free semi-synthetic diet supplemented with methyl retinoate (3 µg per g diet); other groups of birds were fed a similar diet either unsupplemented or containing retinyl acetate (3 µg per g diet).

All the birds fed unsupplemented diet died before the fifth week of the experiment after showing typical signs of vitamin A deficiency<sup>3</sup>. The birds fed methyl retinoate or retinyl acetate grew well, many being maintained in apparent good health on these régimes for longer than 20 months.

After reserves of retinol acquired before hatching had been exhausted at 4–5 weeks of age, the birds maintained with methyl retinoate showed a progressive failure of vision. Abnormal dilatation of the pupils in dim light was first noticed when the birds were 9 weeks old, and by 17 weeks of age their vision in bright light, as assessed by behaviour and pupil size, was severely impaired. At 20 weeks the birds were judged to be almost completely blind.

The retinae in these birds did not undergo irreversible anatomical deterioration at the same rate as has been observed in the retinol-deficient rat<sup>2</sup>. A slight reduction in density of the rod-cone layer was the only detectable histological change in the retinae of birds maintained with retinoic acid for up to 20 months, and after this time, recovery of vision, as judged from pupil responses and behaviour, was complete 7 days after dosing with retinyl acetate.

Cockerels maintained with methyl retinoate and examined at various stages of maturation had testes of normal histological appearance. Semen containing highly motile spermatozoa was regularly obtained from adult cocks and was used to inseminate normal hens and fertilize their eggs successfully. The testes of the cock are thus unlike those of the rat<sup>4</sup> in that they develop and remain healthy in the absence of retinol.

Hens maintained with methyl retinoate laid eggs at a normal rate and, after insemination with semen from normal cocks, eggs with high fertility were obtained from them. However, in these eggs normal embryonic development was seen during only the first 48 h of incubation. Embryos examined at this stage had a normal macroscopic appearance, but older embryos were abnormal in form and showed evidence of gradual disintegration. A conspicuous feature of these eggs was their failure to develop an organized circulatory system in the area vasculosa.

Some of the eggs from hens maintained with methyl retinoate were injected before incubation with solutions of retinol, retinyl acetate or retinal (vitamin A aldehyde) (0.25 or 0.5 mg) in oil. All these substances stimulated normal development in a high proportion of the eggs so injected, and in some instances normal chicks were hatched.

The failure of the embryos to develop normally in un-injected eggs from hens fed methyl retinoate is concluded to be a manifestation of vitamin A deficiency in the early embryo. Vitamin A has thus at least two important roles in avian reproduction: one is the well-known effect on egg production, and the second is this hitherto undescribed role in embryonic development. Methyl retinoate fed to the hen is able to maintain egg production but does not meet the requirements of the embryo. Hitherto, it has not been possible to demonstrate vitamin A deficiency in the chick embryo, because on deficient diets the relatively high requirement of vitamin A for egg production results in hens going out of lay before the vitamin stores in the eggs are reduced sufficiently to affect the development of the early embryo<sup>5</sup>.

Free retinoic acid was found to be extremely toxic to early chick embryos. As little as 1 µg injected into normal fertile eggs prior to incubation prevented development. The injections appeared to result in disintegration of the entire early blastoderm. Much larger quantities of retinol (> 0.5 mg) were required to produce a similar effect. Methyl retinoate was found to be similar to retinol in its relative lack of toxicity.

The toxicity of free retinoic acid and retinol in the egg is probably related to that observed in the rat<sup>6</sup>, in *Xenopus laevis*<sup>7</sup> and in chick limb rudiments in tissue culture<sup>8</sup>.

It is unlikely that the toxic action of retinoic acid is responsible for the failure of embryos to develop in eggs from hens maintained with methyl retinoate. Such embryos can be stimulated to grow normally by injecting retinol; also the two abnormalities are dissimilar both in macroscopic appearance and in time of onset. It is concluded that the early chick embryo is very susceptible to conditions of both hyper- and hypo-vitaminosis A.

### Decomposition of Structural Polysaccharides of Bacteria by Marine Micro-organisms

THE large numbers of bacteria which are carried into the sea in sewage and land drainage survive for only a short period of time<sup>1</sup>. Both physicochemical<sup>2</sup> and biological<sup>3</sup> factors have been implicated in the bactericidal effect. Saz *et al.*<sup>4</sup> have demonstrated the presence in natural sea water of macromolecular particles with activity against *Staphylococcus aureus*. The decline of *Shigella* in natural sea water has also been correlated with the presence of antibacterial macromolecules in the water<sup>5</sup>.

While examining biological degradation of a *Flavobacterium* capsular polysaccharide<sup>6</sup>, it was observed that a bacterium isolated from soil which was active against the capsular material also caused complete liquefaction of agar. This bacterium was a short Gram-negative rod which was classified as a species of *Pseudomonas*. A bacterium isolated from soil by Sickles and Shaw<sup>7</sup> was capable of degrading capsular polysaccharide of *Pneumococcus* type III, and also decomposed agar. These observations suggested a correlation between microbial degradation of agar and decomposition of structural material of bacteria. Stanier<sup>8</sup> has demonstrated the presence in sea water of a large and varied population of agar-decomposing bacteria. Consequently an investigation was initiated to determine whether micro-organisms which degrade both agar and bacterial structural materials could be isolated from natural sea water.

Enrichment cultures were prepared using natural sea water from the Mediterranean near Ashkelon as the inoculum in ZoBell's<sup>9</sup> artificial sea water medium containing *Flavobacterium* capsules as the sole carbon source. These enrichments resulted in the isolation of a halophilic marine *Pseudomonas* capable of utilizing *Flavobacterium* capsular polysaccharide as its sole carbon source. Similar bacteria capable of growth on capsules of *Azotobacter*, *Rhizobium*, *Arthrobacter*, and cell walls of *Escherichia coli* 'B' were also isolated from sea water by enrichment on the respective structural materials. All isolates caused complete liquefaction of agar. Capsular material used in these investigations was prepared by repeated extraction with 10 per cent trichloroacetic acid at 0° C. The capsules were re-precipitated in 66 per cent ethanol following extraction of the trichloroacetic acid in ether. Cell walls of *E. coli* 'B' were prepared by extrusion in a French press. The walls were washed repeatedly in buffer.

The marine bacterium isolated from *Flavobacterium* capsule medium grew well on *E. coli* 'B' cell walls. Oxygen uptake during growth of this bacterium was measured in the Warburg microrespirometer in ZoBell's medium. Both capsules and cell walls were metabolized. During the logarithmic growth phase 75 µl. O<sub>2</sub>/h was consumed by the bacterium growing on capsular material,

Fig. 1. Survival curves of *Escherichia coli* 'B' (O) and *Arthrobacter* (Δ) in ZoBell's artificial sea water medium in the presence of a lytic marine *Pseudomonas*. *R* represents the ratio (%) between optical density of *Esch. coli* 'B' and *Arthrobacter* samples in nutrient broth following sub-culture from ZoBell's medium inoculated with the marine *Pseudomonas* and of the optical density of samples from ZoBell's medium without the marine bacterium

and 252  $\mu$ l./h during growth on *E. coli* 'B' cell walls, following correction for endogenous respiration. No respiration was detected in flasks inoculated with a soil bacterium capable of utilizing a wide range of carbon sources, indicating the absence of non-specific contaminants in the substrate material.

Tests for enzymatic activity were carried out using culture filtrates and sonicated cells of the marine *Pseudomonas* following growth on ZoBell's medium containing nutrient broth (Difco), *E. coli* 'B' cell walls, *Flavobacterium* capsular polysaccharide and agar as the respective carbon sources. Polysaccharidase activity was detected by release of reducing sugars using the method of Somogyi<sup>10</sup> and Nelson<sup>11</sup>. Release of free amino-groups from *E. coli* 'B' cell walls was detected by the method of Moore and Stein<sup>12</sup>. Polysaccharidases active against *Flavobacterium* capsular material and agar were produced extracellularly. Detectable quantities of enzyme accumulated in the culture media after three days of incubation in shake culture. No polysaccharidase activity was detected in sonicated cells. Free amino-groups were released during decomposition of *E. coli* 'B' cell walls by sonicated cells of the *Pseudomonas*, following 24 h incubation in shake culture, indicating that the enzymatic system active against *E. coli* 'B' walls was intracellular. Preparations of the *Pseudomonas* displayed activity against *Flavobacterium* capsular polysaccharide, agar and *E. coli* 'B' cell walls only following growth on the respective substrate. These data provide evidence that the enzyme systems causing degradation of each of the four substrates were inducible.

One of the marine bacteria isolated in this investigation grew well on capsular polysaccharides of a heavily encapsulated strain of *Arthrobacter*, a bacterium commonly found in the soil. The marine organism also utilized *E. coli* 'B' cell walls. Activity of this marine bacterium against living cells of each of the two non-marine bacteria was tested by growing the bacteria together in ZoBell's artificial sea water medium fortified with 0.1 per cent peptone. Survival of the non-marine bacterium was determined by daily sub-culture to nutrient broth (Difco) prepared with tap water. The marine bacterium was unable to grow on this medium. The results shown in

Fig. 1 demonstrate the survival of *Arthrobacter* and *E. coli* 'B' in artificial sea water in the presence and absence of the marine bacterium, as expressed by the *R* value. Both non-marine bacteria were markedly suppressed by the marine bacterium. The greater resistance to lysis of the *Arthrobacter* may be attributed to its capsular layer, but it is not clear if lysis results from degradation of the capsule alone or in addition to degradation of the underlying cell wall.

The relationship between degradation of these structural materials and agarase activity, and the significance of these findings in marine ecology, are at present being investigated.

### Free Radicals derived from Amines and Amino-acids in some Reactions of Ninhydrin

ALLOXAN and dialuric acid form free radicals in alkaline solution<sup>1,2</sup>. Ninhydrin, a chemical analogue of alloxan, has been shown to form a free radical on reaction with glycine<sup>3</sup>. The electron spin resonance (ESR) spectrum of this radical consists of 9 lines and is attributed to the two pairs of equivalent benzenoid protons of ninhydrin.

I have observed that the same radical can be produced directly by treating a molar solution of ninhydrin in methanol with 5 N aqueous sodium hydroxide. A red precipitate forms which is unstable in air. The ESR signal is associated with this precipitate. In the presence of excess alkali this precipitate turns blue and the ESR signal disappears. MacFadyen and Fowler<sup>4</sup> observed the same colour changes in alkaline solutions of hydrindantin. They also noted the sensitivity of the red compound to air. They attributed the red and blue colours to the mono- and di-valent anions of indanone-ene-diol. I have found that when hydrindantin is treated with normal potassium hydroxide, or dissolved in buffer at pH 9.0, the red solution obtained gives an intense ESR signal identical to that described above. The blue solution obtained under more strongly alkaline conditions gives no signal. It seems probable that the free radical described above is the semi-quinone anion of indanone-ene-diol.

I have also observed that this radical appears in the reaction of ninhydrin with ethylamine, *n*-butylamine, dimethylamine and diethylamine. Other free radicals

is due to the benzenoid protons of the ninhydrin portion of the following free radical; splitting constants (gauss) are shown in brackets.

The splitting constants attributed to the benzenoid protons of this radical (Fig. 1c) are 0.7 and 0.47 gauss compared to those of 0.94 and 0.74 gauss in the ninhydrin-free radical shown in Fig. 1d.

Fig. 1. *a*, First derivative of the ESR absorption of the free radical obtained from the reaction of dimethylamine with ninhydrin. *b* and *c*, Part of *a* under progressively higher resolution. *d*, First derivative of the ESR absorption of the ninhydrin-free radical

sociated with the amine can also be detected, but they decay rapidly. No free radicals were observed when tertiary amines were investigated.

The ESR spectra were studied using flat 'Pyrex' tubes inserted into an  $H_{012}$  cavity of a Hilger-Watts Microspin-band spectrometer utilizing 100-ke/s modulation. Fig. 1*a* shows the ESR spectrum obtained when equimolar quantities of dimethylamine and ninhydrin in methanol were gently warmed. The spectrum covers 70 gauss peak to peak and shows 9 equally spaced lines 8.8 gauss apart. The intensity ratios of these lines are 7:22:41:50:41:22:7:1 and correspond to those expected from the equal coupling of an unpaired electron between one nitrogen atom and six protons. Figs. 1*b* and 1*c* show part of the spectrum under progressively higher resolution. Each peak appears first as a quintet and then nine lines. It is suggested that this hyperfine structure

Fig. 2. *a*, First derivative of the ESR absorption of the free radical obtained from the reaction of sarcosine with ninhydrin. *b*, Three peaks in the wings of *a* under higher resolution

When ninhydrin is reacted with certain amino-acids under alkaline conditions free radicals are formed which are believed to have similar structures to that suggested above. Fig. 2*a* shows the ESR spectrum obtained when aqueous solutions of sarcosine (molar) and ninhydrin (0.3 molar) are mixed in equimolar amounts and made alkaline (pH 8.5) with normal sodium hydroxide. Thirteen equally spaced lines covering 58-gauss peak to peak are obtained in low resolution. The spectrum can be empirically attributed to coupling of an unpaired electron between the nitrogen atom and the five protons of sarcosine. The radical could have the following structure, approximate coupling in gauss:

It has not yet been possible to observe this radical without some distortion of the centre peak of the spectrum due to the presence of the unbound free radical from ninhydrin. However, the intensity ratios observed are 1:2:4:7:8:11:12:15:9:8:5:2:1 which may be compared with 1:2:5:8:11:14:14:14:11:8:5:2:1 expected for the coupling suggested.

Fig. 2b shows the appearance of the peaks in the wings of the spectrum under high resolution. It is suggested that this hyperfine splitting results from the benzenoid protons in the ninhydrin part of the complex. The centre triplet is not resolved, but the two splitting constants 0.75 gauss and 0.47 gauss are not significantly different from those observed in the dimethylamine reaction.

Other spectra have been observed from L-proline (11 lines 55-gauss total splitting) and L-hydroxyproline (12 lines 55-gauss total splitting). The reaction of aspartic acid with ninhydrin under similar conditions to those described above yields a three-line spectrum covering 13.4 gauss. This is probably due to a single nitrogen atom of coupling constant 6.7 gauss and a different type of radical structure from that suggested above is probably involved.

I thank Dr. R. Foster and Dr. R. Jameson of the Chemistry Department for their advice.

### Tumours in the Rat after Injection of Preneoplastic and Neoplastic Nucleic Acids

SOME years ago, it was reported from our laboratories that lymphosarcomas developed at the site of subcutaneous injection of a chromatin fraction obtained from Murphy lymphosarcoma cells, and that hepatomas appeared at the site of intrahepatic injection of a similar fraction obtained from cells of a transplantable hepatoma<sup>1-3</sup>. The significance of these observations was questioned on the grounds that the possibility of the presence of intact cells in the injected material could not be excluded with certainty.

Since then, there have been several reports of induction of tumours by nucleic acids of oncogenic viruses<sup>4-10</sup>. There is evidence, too, that other types of biologically active nucleic acid molecules can penetrate somatic cells and can alter synthetic processes<sup>11-18</sup>, the nature of the observations in certain instances suggesting that exogenous DNA had entered the recipient genome. Accordingly, the concept of transfer of subcellular genetic entities from one mammalian cell to another is no longer regarded as fanciful, as it was at the time of our initial reports.

The present study was undertaken to investigate the following possibilities: (a) that the malignant potentialities of 'preneoplastic' liver cells may be transferred to normal cells by intrahepatic injection of 'preneoplastic' nucleic acids; (b) that the malignant properties of hepatoma cells

may be transferred to normal cells by incubation with hepatoma nucleic acids.

Nucleic acids were prepared from two sources: (a) the Morris hepatoma 3924C, carried in  $A \times C$  rats; (b) 'preneoplastic' liver, that is, livers of male rats that had received 2-acetylaminofluorene (0.03 per cent) in the diet for 90 days, followed by a carcinogen-free diet for 30 days, at which time (120 days) there is no detectable morphological evidence of malignancy in the liver. With this AAF dosage and the diet used, hepatomas develop ultimately in 85 per cent of male rats, the earliest in our experience having been at 156 days.

DNA was prepared by the method of Colter, Brown and Ellem<sup>11</sup>, and RNA by the method of Kirby<sup>18</sup> from tissues (liver; tumour) which had been frozen in a dry-ice/alcohol mixture immediately after removal. The remaining procedures were carried out at 4°C. The DNA was undoubtedly contaminated by a small amount of RNA, no attempt having been made to achieve purity of the preparation.

Two types of experiment were performed: (1) intra-hepatic injection of cells of regenerating liver that had been incubated with hepatoma nucleic acids; (2) intra-hepatic injection of nucleic acids of hepatoma and of 'preneoplastic' liver. In the former case, adult male  $A \times C$  rats (200 g) were partially hepatectomized<sup>19</sup> and were killed 72 h later. Regenerating liver (2 g) was disrupted in 20 ml. of Hanks's solution in a Potter-Elvehjem homogenizer with a loosely fitting 'Teflon' pestle, and was mixed thoroughly with 50 mg of hepatoma DNA or RNA. The cell suspension was incubated in a shaking incubator for 2 h at 37°C and was then centrifuged; 0.1 ml. of the packed cells was injected into the liver in 120 male  $A \times C$  rats (150 g) under ether anaesthesia. The injection site was sealed with 'Surgicel'. The rats were killed after 2-8 months.

In the second type of experiment approximately 50 mg of DNA or RNA was placed in 5 ml. saline and dissolved by vigorous mechanical stirring; 0.1 ml. (approximately 1 mg) nucleic acid was injected into either the intact liver or the regenerating liver (72 h after partial hepatectomy of 150-g male  $A \times C$  rats under ether anaesthesia. The injection site was sealed with 'Surgicel'.

Hepatoma nucleic acids were employed in 160 intact and 60 partially hepatectomized rats, which were killed 8-16 weeks later. 'Preneoplastic' liver nucleic acids were used in 110 intact and 40 partially hepatectomized animals, which were examined at laparotomy after 4 months and were killed after 6 or 8 months.

Tumours were found in two animals at the site of injection of cells of regenerating liver that had been incubated with hepatoma DNA, one 10 weeks and the other 16 weeks after injection. Both were well encapsulated and measured 1.5 cm in diameter. Their morphological characteristics closely resembled those of tumours produced by intrahepatic injection of intact cells of the hepatoma from which the DNA had been obtained. On important difference was in the time required for development of tumours of comparable size following injection of comparable numbers of hepatoma cells, which is about 3 weeks, in contrast to 10 and 16 weeks in the case of the induced tumours.

A tumour occurred in one animal in which a mixture of 'preneoplastic' liver DNA and RNA had been injected into the regenerating liver 6 months previously. It was 2.5 cm in diameter and well encapsulated, presented ventrally beneath the skin of the upper abdomen, and was adherent to the anterior surface of the liver. It was examined by a number of pathologists experienced in rodent tumours. All agreed that it was a malignant neoplasm, different from any seen previously by them in the rat, but there was no agreement as to its nature beyond this.

The most important implication of these findings is that the observed tumours represent a process of true genetic

transduction, involving genic recombination mechanisms similar to those established in the case of certain bacteria. However, other possibilities must be considered: (1) that they are spontaneous tumours, unrelated to the experimental procedure; (2) that they arose as a result of transfer, into the incubated cells or injected liver, of carcinogen (AAF) bound to the nucleic acids; (3) that they represent tumour production by a virus or by viral nucleic acid rather than by liver or hepatoma nucleic acids.

The recent report of the production of mammary tumours in rats by injection of nucleic acids and cell-free preparations of mammary cancers induced by 7,12-dimethylbenzanthracene implies viral involvement in the production of these tumours<sup>20</sup>. This possibility cannot be excluded in the present instance. However, it seems unlikely because of (a) the very low incidence of induced tumours and (b) the fact that attempts to produce tumours by intraperitoneal or intramuscular injection of cell-free saline extracts of the original hepatomas have invariably been unsuccessful.

There is no precise information as to how much, if any, AAF is bound to liver nucleic acids 30 days after discontinuing administration of the carcinogen. There is, therefore, no certainty that minute amounts may not have been introduced into the liver with the 'preneoplastic' liver nucleic acids and possibly, albeit remotely so, contributed to the development of the peculiar tumour of undetermined nature several months later. Nor can one exclude the possibility of spontaneous origin of this tumour.

In the case of the two hepatomas, however, the first of these two possible mechanisms does not apply and the second seems highly improbable because of (a) their fibrous encapsulation and localization at the site of injection, and (b) their development within only 10 and 16 weeks after the liver had been seen to be grossly normal at laparotomy. It seems reasonable to conclude that these two tumours were induced by the experimental procedure and that the probability is strong that a process of genetic transduction was involved in their pathogenesis.

We thank Dr. Harold L. Stewart, National Cancer Institute, for his advice. This investigation was supported by U.S. Public Health Service grant CA-07212-01 from the National Cancer Institute.

## Denaturation of Rennin ; Effect on Activity and Molecular Configuration

RENNIN has an optimum pH of 3.4 for the proteolysis of bovine serum albumin<sup>1</sup> and 3.8 for poly-L-glutamic acid<sup>2</sup>. At pH values between 5 and 7 it will coagulate milk and slowly attack casein. It has maximum stability at pH 5.4, while at values above 7 it loses activity rapidly.

Titration of a solution of rennin (crystalline enzyme prepared as described by Berridge and Woodward<sup>3</sup>, 11.5 mg/ml.) from pH 5.4 to pH 8.5 at room temperature, by means of a 'pH Stat', results in a further uptake of alkali after titration to an alkaline pH. It was found that the uptake at pH 8.5 had ceased after further addition of NaOH equivalent to 3.4 mole per mole enzyme (assumed mol. wt. 32,000). The increase in titratable groups suggests that after loss of enzyme activity there are relatively slow changes involving unmasking of groups presumably by the unfolding or splitting of the enzyme molecule. The

increase in viscosity number  $\left(\frac{V/V_0 - 1}{c}\right)$  from 5.25 at

pH 5.85-7.85 at pH 8.2 also indicates change in molecular configuration. The increases in viscosity number occur when the enzyme is initially taken to the higher pH value. On standing at pH 8.2 for 18 h and 65 h the viscosity number falls to 7.5 and 4.9 respectively. Further confirmation of possible changes, intra- and/or intermolecular, is indicated by the measurement of ultra-violet absorption which shows a 23 per cent fall in the absorption at 280 mμ, a 19 per cent fall in absorption at 290 mμ, and a 50 per cent increase in absorption at 250 mμ, after keeping a solution of the enzyme at pH 8.5 for 24 h.

Electrophoresis patterns of (a) active enzyme, (b) inactive enzyme immediately after treatment to pH 8.5, and (c) after being held at pH 8.5 for 24 h (Fig. 1) show that the active and inactive enzyme have similar mobility and that after 24 h at pH 8.5 other bands probably due to fragmentation of the enzyme appear.

Determination of the number of disulphide linkages in the enzyme molecule by the performic oxidation method

Fig. 1. Electrophoresis patterns of rennin and alkali-treated rennin in 5 per cent polyacrylamide gel, 0.005 M tris/citrate buffer pH 7.0. Run at 300 V for 5.5 h. Protein was stained with amido black. a, Active enzyme; b, inactive enzyme immediately after treatment at pH 8.5; c, after 24 h at pH 8.5.

Fig. 2. The relationship of the pH of reaction with reduction of disulphide bonds and loss of activity. Open circles indicate reduction and closed circles activity. 100 per cent reduction is equivalent to one disulphide bond per enzyme molecule. The molecular ratio of  $\beta$ -mercaptoethylamine to enzyme was about 1,000 : 1

as modified by Moore<sup>4</sup> indicates three bonds per 32,000 mol. wt. No free -SH groups can be detected. However, investigation into the reactivity of the disulphide bonds shows considerable differences in their availability to reduction. When the enzyme is subjected to reduction with  $\beta$ -mercaptoethylamine at various pH (see Fig. 2) the maximum reduction occurs at pH 9.8 and is equivalent to one disulphide bond per molecule. Increasing the period of reduction from 1 h to 3 h did not increase this figure. Complete inactivation of the enzyme occurred one pH unit lower than that which gave maximum reduction. At this lower pH about 75 per cent of the possible reduction had occurred. By using sodium dodecyl sulphate dissolved to saturation in the buffer at pH 7, the quantity of disulphide reduced by  $\beta$ -mercaptoethylamine was increased to the equivalent of two linkages per molecule. Dissolving the enzyme in buffer saturated with guanidine HCl made one linkage available for reduction independent of the buffer pH. It was not possible under the conditions used to obtain reduction of all three disulphide bonds.

Enzyme activity is rapidly and irreversibly lost in the presence of urea. More than 50 per cent of the activity of *B*-rennin (isolated from crystalline rennin<sup>5</sup>) was lost in 30 min incubation at 37° in 4.6 M urea (see Fig. 3). Comparison with pepsin, an enzyme of similar molecular size containing three disulphide linkages<sup>6</sup>, shows that pepsin is more stable than rennin at the same urea concentrations. The total milk-clotting activity of commercial rennet after urea treatment is greater than the purified enzyme,

Fig. 3. Inactivation of *B*-rennin, commercial rennet and pepsin in urea at pH 5.4. ○, *B*-rennin activity; ●, rennet activity; △, pepsin activity. The broken line indicates activity in 4.6 M urea and the full line indicates activity in 6 M urea. The activity of pepsin in both 4.6 M and 6 M urea was similar

presumably owing to the presence of pepsin or other similar milk-clotting enzymes.

This series of observations shows that rennin activity is lost rapidly under relatively mild conditions such as do not denature all proteins, and that the loss is associated with minimal changes in molecular configuration. Prolonged treatment under the same conditions gives rise to further changes in configuration and finally to fragmentation of the molecule.

## PHYSIOLOGY

### Comparison of Multiple-unit and Electroencephalogram Activity recorded from the same Brain Sites during Behavioural Conditioning

IN an attempt to find a more sensitive measure of brain activity than that yielded by EEG recordings, and sample more extensively than is possible with single unit, micro-electrode recordings, we have examined multiple-unit activity recorded and integrated from various brain sites in cats during behavioural conditioning procedures. Multiple-unit recordings of central activity have been made in acute<sup>1,2</sup> and in chronic<sup>3</sup> preparations, but this technique has not been used in learning experiments<sup>4</sup>. In the work reported here, multiple-unit discharge was picked up by chronically implanted stainless steel insect-pin electrodes, amplified, and recorded on one beam of a Tektronix 502 oscilloscope. This unit activity was concurrently integrated and the output of the integration circuit recorded on the second beam of the oscilloscope. Simultaneously with these recordings, EEG activity was picked up through the same electrode and written out on a Grass model IIG EEG machine. In this communication a comparison will be made between the multiple-unit and EEG activity recorded from the same brain sites during the acquisition and extinction of a conditioned hindleg flexion response.

In Fig. 1, the multiple-unit activity of the medial geniculate body is illustrated on the left, while the EEG activity recorded concurrently through the same electrode is displayed on the right. Immediately below the multiple-unit activity, its integration is displayed a rise in the line of integrated activity corresponds to an increase in unit discharge, while a drop in the line indicates decreased activity. The first traces were recorded during the habituation of a chronic cat to a 1.5 sec, 1,500-c/s tone. As can be seen, a marked inhibition of geniculate unit discharge is produced by the tone and concurrently the integrated multiple-unit activity shows a marked depression. In contrast, the concomitant EEG recording indicates very little effect of tone presentation.

During subsequent training procedures, the 1,500-c/s tone (CS) was paired with a 0.5 sec, 60-c/s shock to the left hind paw (US) to establish a conditioned flexion response. In the second line of Fig. 1 traces are shown from a trial early in training prior to the appearance of overt conditioned responses. The multiple-unit activity is no longer inhibited and the integrated activity remains at a constant level during the CS presentation. Although this lack of response represents a significant shift from

## HABITUATION

## EARLY TRAINING

## LATE TRAINING

## EXTINCTION

Fig. 1. Multiple-unit activity recorded and integrated from the medial geniculate nucleus (left) with concurrent recording of the EEG through the same electrode (right). Bars over traces indicate durations of 1.5 sec tone (CS: first and fourth traces) and CS paired with 0.5 sec shock to the hindpaw (US: second and third traces). The habituation excerpts are from the sixteenth habituation session. Activity during early training is shown by traces from trial 19 of the first conditioning session. The late training trial represents activity during performance of an overt conditioned response after the performance level had been maintained at 90 per cent or better for two prior sessions. The extinction trial is excerpted from the first extinction session, after disappearance of the overt response.

the inhibited unit discharge produced during habituation, no corresponding change is reflected by EEG activity.

Traces recorded during a trial later in training, after overt conditioned responses had been established, are shown in the third line of Fig. 1. A sharp acceleration of unit discharge is now consistently elicited by the CS and the integrated unit activity increases correspondingly. The EEG shows a slight desynchronization, but this was constantly present in spite of the persistent unit acceleration.

In the fourth line, traces are shown from a trial during subsequent extinction, after the overt conditioned responses had disappeared. The direction of unit response was again shifted markedly. Inhibition is once more produced by the CS and, concurrently, the integrated activity drops markedly. The EEG during CS presentation, however, shows little that would distinguish it from the pre-CS period.

These sample recordings indicate that a progression of marked and oppositely directed changes in medial geniculate neuronal activity occur during various phases of behavioural conditioning and, by integration of the unit activity, these changes can be quantitated. EEG activity recorded simultaneously from the same site shows no alterations corresponding to the changes in multiple-unit activity, nor does the EEG suggest any other consistent response progression during the various training sequences. Similar results have been obtained from recordings in three other animals with histological verification of electrode placements in the medial geniculate nucleus.

In nine chronically implanted cats at present under examination, several other sites have shown the development of characteristic changes in multiple-unit activity during conditioning but no consistent or definite alterations in EEG activity at the same site. In Fig. 2, activity from the nucleus ventralis postero-lateralis (VPL) of the thalamus is represented by multiple-unit discharge in the upper trace and EEG activity, simultaneously recorded from the same electrode, in the second trace. In the third trace, EMG activity from the hamstring muscles of the

## N. VENTRALIS POSTERO-LATERALIS

## N. ANTERIOR VENTRALIS

Fig. 2. Multiple-unit activity recorded and integrated with concurrent EEG from thalamic nucleus ventralis postero-lateralis during a conditioned flexion of the hindleg. Durations of 1.5 sec CS and 0.5 sec US are indicated by bars over traces. The EMG, recorded from the hamstring muscles of the responding leg, has the same time base as the EEG. Multiple-unit activity recorded and integrated with concurrent EEG from thalamic nucleus anterior ventralis during a conditioned flexion response. The EMG is recorded from the hamstring muscles of the responding leg.

'conditioned' hindleg is shown. During the conditioning trial illustrated, a marked increase in unit discharge and in the integrated activity-level is elicited by the CS concurrently with EMG activation and an overt conditioned response. The EEG, however, remains essentially unchanged during this trial as well as during other trials in which accelerated unit discharge accompanied the overt responses.

In contrast to the development of multiple-unit conditioned discharge in such thalamic sites as the medial geniculate and VPL nuclei, in other thalamic areas, such as the nucleus anterior ventralis (AV), the CS caused no change in unit activity even when overt conditioned responses were consistently being made. In the lower half of Fig. 2, the multiple-unit spike activity and integration recorded from the AV nucleus remain essentially unchanged during a CS presentation (upper trace), although EMG activation and an overt conditioned response are produced. EEG activity recorded from the same site (middle trace) shows a slight desynchronization to the CS, but this response was not constantly present.

Recordings from 23 brain sites sampled in nine chronic cats have shown that during behavioural conditioning procedures marked changes in multiple-unit activity frequently occur without any distinct or consistent change in the EEG recorded from the same site. Thus, multiple-unit recording not only provides a greater sample of spike activity than does single-unit recording, but also it would seem to be a much more sensitive index of changing neuronal activity than is the EEG. Moreover, by appropriate integration of the multiple-unit activity, a measure of neuronal activity is provided which allows a quantitative comparison of activity-levels at a particular brain site from one training sequence to the next or, during a particular training session, simultaneous comparison of activity-levels at a number of brain sites is possible.

### Salivary Secretion of Caesium-131

In previous investigations it has been shown that potassium-42 and rubidium-86 are rapidly cleared from the blood and secreted into the saliva in identical fashion<sup>1,2</sup>. This has led to the development of techniques for the determination of exchangeable potassium with <sup>42</sup>K or <sup>86</sup>Rb, using saliva rather than urine, since urinary excretion of these two isotopes differs<sup>3</sup>. In an investigation of the applicability of the recently reactor-produced caesium-131 (physical half-life, 9.5 days; 29.4-keV X-ray) as a substitute for the short-lived gamma-emitters <sup>42</sup>K (physical half-life, 12 h) and the relatively long lived <sup>86</sup>Rb (physical half-life, 18.6 days) differences in the salivary excretion of <sup>131</sup>Cs and <sup>42</sup>K or <sup>86</sup>Rb were noted.

Tracer doses of <sup>131</sup>Cs were given to six control subjects in 50 ml. tap-water by mouth. Saliva was collected at various times thereafter starting at 14 h, the subject chewing on a small piece of paraffin for at least 2 min to establish an even flow of saliva. Samples of saliva were then collected for counting in a deep-well scintillation counter. Urine was collected for the entire period of observation to correct for excretion of <sup>131</sup>Cs.

Stable potassium (<sup>39</sup>K) in saliva was determined by flame photometry. 'Exchangeable potassium' was calculated as follows:

$$\frac{{}^{131}\text{Cs } \mu\text{c. administered} - {}^{131}\text{Cs } \mu\text{c. excreted}}{{}^{131}\text{Cs } \mu\text{c. l. saliva}/{}^{39}\text{K m.equiv./l. saliva}}$$

Table 1 shows the results of seven tests in the six control subjects. Predicted values for exchangeable potassium (Ke) were derived from Allen *et al.*<sup>3</sup> and Sagild<sup>4</sup>, who demonstrated a linear decrease in total body potassium of 17 m.equiv. a year for men and 10 m.equiv. a year for women.

\* Actual determinations.

The data show that <sup>131</sup>Cs is secreted in the saliva in an unpredictable manner as compared with <sup>42</sup>K and that at no time does there appear to be complete equilibration. The fluctuations of <sup>131</sup>Cs excretions in saliva from one collection period to the next are much greater than those of <sup>42</sup>K. An unexplained transient dip in specific activity and rise in exchangeable potassium values after 20 h was noted in four of five tests in which multiple collections were done. This is not due to diurnal variation because the tracer doses were given at various times of day.

Fig. 1 shows the specific activities:

$$\left( \frac{{}^{42}\text{K } \mu\text{c./l.}}{{}^{39}\text{K m.equiv./l.}} \right) \text{ and } \left( \frac{{}^{131}\text{Cs } \mu\text{c./l.}}{{}^{39}\text{K m.equiv./l.}} \right)$$

in two control subjects plotted against time. One of the subjects had received 400  $\mu\text{c.}$  <sup>42</sup>K and the other 400  $\mu\text{c.}$  <sup>131</sup>Cs. It is apparent that the rate of equilibration of these two isotopes in saliva is similar, so that the reduced secretion of <sup>131</sup>Cs must be due to a mechanism other than delayed equilibration.

Fig. 1. Specific activities of <sup>42</sup>K/<sup>39</sup>K and <sup>131</sup>Cs/<sup>39</sup>K in two control subjects

It is concluded that the salivary glands secrete  $^{131}\text{Cs}$  qualitatively and quantitatively differently from  $^{42}\text{K}$  or  $^{86}\text{Rb}$  and that  $^{131}\text{Cs}$  cannot be used for salivary estimation of exchangeable potassium.

$^{131}\text{Cs}$  was generously supplied by Abbott Laboratories, North Chicago, Illinois.

### Distribution of Dendrites in Retinal Ganglion and Cortical Stellate Cells

THE large multipolar ganglion cells of the retina send their dendrites in all directions over a wide area in the inner molecular layer. The general features of these cells have been investigated in many different vertebrates by numerous investigators<sup>1-3</sup>. Polyak<sup>3</sup> has given the fullest description, grouping the cells according to the extent and complexity of the dendritic processes when viewed in vertical section. Ramón y Cajal's original description grouped them chiefly according to the depth at which most of their dendrites were found in the inner molecular layer. Oshinomi<sup>4</sup>, probably because of the inherent difficulties of demonstrating the dendrites, relied solely on the size and shape of the body to place them in different categories.

It would seem that the purpose of these extensive dendritic branches is to derive impulses from areas of the retinal surface adjacent to the cell body. The extent and distribution of these branches in such an area can only be seen completely in whole mount preparations, stained by means of Ehrlich's methylene blue method. Apart from Dogiel's extensive investigations and the investigations of Kolmer<sup>5</sup>, Sorsby<sup>6</sup> and Polyak<sup>3</sup>, the retina has been little investigated by this method in recent years. Dogiel considered that the dendritic branches form a syncytial network and consequently this 'nerve net' theory precluded him from investigating the distribution of dendrites associated with individual cells. Now that it is known that the dendritic branches do not unite with each other, the determination of their distribution can provide a means of estimating the degree to which adjacent neurones are interrelated.

With this in view, Sholl<sup>7</sup> recently sought to explain the way in which incoming impulses are analysed by the visual cortex by determining the length and arrangement of the dendritic branches of the pyramidal and stellate cells found within it. Apparently these cell dendrites initially increase rapidly in numbers to a radius of about  $0\mu$  from the cell and, at greater distances, later decline slowly. Since the large multipolar ganglion cells of the retina also resemble the cortical cells, it seemed desirable to investigate the changes in their dendritic distribution to discover whether similar phases of dendritic proliferation and decay were common to other parts of the visual pathway.

To make a simple comparison between the cortical neurones and the ganglion cells of the retina, the average rate of branching of a dendrite at a given distance from the cell body was determined. This value will be referred to as the branching coefficient  $\lambda$ , being the fractional rate

at which branches were gained or lost per micron of radial distance from the cell. The branching coefficient was calculated for cortical cells from the data of Sholl, and for retinal ganglion cells it was found by measuring the dendritic processes in whole mount preparations of the rabbit retina. The positions of the dendrites were plotted by means of a camera lucida with a ruled graticule in the eyepiece of the microscope. Flatness of the field and its dimensions were checked by means of a stage micrometer.

These preliminary observations show that there are marked quantitative differences between the dendrites of cortical and retinal cells. The differences are illustrated in Figs. 1 and 2.

Fig. 1

Fig. 2

At a distance of about  $30\mu$  from the cell body the fractional rate of formation of new branches is about the same in both retina and cortex. Afterwards, the cortical cells suffer an almost immediate loss of branches while the retinal cells continue to add new branches to their dendrites. Since the rate of branch formation in both regions near the cell body is similar, branching here may be controlled mainly by the cell itself. At greater distances, the influence of the cell becoming progressively weaker, other factors govern the dendritic branching and account for a decline in the cortical and a gain in the retina branches.

It will be seen from Fig. 1 that the dendrites of the ganglion cells show a continuous and rapid rate of proliferation for about half their course and thereafter lose their branches at about the same rate.

In Fig. 2 the cortical cell dendrites show a prolonged region some three times as extensive as ganglion cells where there is a slow continuous loss before they finally terminate. Furthermore, the rate of branching of retinal ganglion cells is about twice as great as cortical cells. This suggests that in the retina dendritic branches of the large multipolar ganglion cells link up with adjacent

areas to a greater extent than do the stellate cells of the visual cortex.

### Delayed Onset of Proteinuria in Ageing Hypophysectomized Rats

THE excretion of protein in the urine of the male rat increases progressively with age<sup>1-3</sup>, the output of protein approximately doubling with each increase of 200 days in age<sup>3</sup>. This rising level of proteinuria in the rat has been associated with the gradual development of chronic nephrosis with advancing age<sup>4</sup>.

It has been shown by Goodman *et al.*<sup>5</sup> that hypophysectomy diminishes spontaneous proteinuria in the young male rat. The present investigation was undertaken to determine whether hypophysectomy performed in early life would permanently restrain the development of proteinuria in the ageing male rat.

At the age of 50 days, a group of 25 male albino rats of the Wistar strain were hypophysectomized using the parapharyngeal approach. Only hypophysectomized animals which gained less than 30 g in 300 days were used in this study. A second group of 25 male rats of the same age acted as controls. All animals were housed in air-conditioned rat quarters ( $27^{\circ} \pm 1^{\circ} \text{C}$  and  $55 \pm 5$  per cent relative humidity) and fed a pelleted diet as described earlier<sup>6</sup>. The urinary excretion of protein was determined a few days before operation and then at the ages of 250, 400, 500 and 600 days. For these estimations rats were placed individually in metabolism cages, and, after an adaptation period of three days, urine was collected for 24 h. Urinary protein was estimated using the trichloroacetic acid turbidimetric method of Henry *et al.*<sup>7</sup>.

At the age of 600 days only 6 hypophysectomized and 23 control rats survived. Protein excretion data from these animals at various ages are shown in Fig. 1. In the 23 control rats the mean protein excretion rose from zero at 48 days to 6.2 mg N per day at 600 days. However, in the 6 hypophysectomized rats no protein was excreted in urine until they were 500 days old, when trace amounts (0.1 mg/day) were detected in 3 animals. At 600 days these

3 rats were excreting 0.2, 0.4 and 1.4 mg respectively of protein N per day; the other 3 hypophysectomized rats in the group were still not excreting any protein.

Seven hypophysectomized rats died between 500 and 600 days and 4 of these excreted respectively 0.1, 0.2, 0.5 and 0.7 mg of protein N at 500 days. Of 12 hypophysectomized rats which died before 500 days two excreted 0.1 and 0.5 mg respectively of protein N at 400 days. Thus a total of 16 out of 25 hypophysectomized rats did not excrete detectable amounts of protein in their urine at any stage in their life-cycle. In some of these animals small fragments of pituitary tissue were observed in the pituitary fossa at autopsy. However, this residual tissue did not appear to be correlated with the excretion of protein.

These results, therefore, indicate that hypophysectomy, performed at 50 days of age, delays the onset of proteinuria in the male albino rat until it reaches the age of 400 days or later. This effect of hypophysectomy is similar to that of food restriction, which delays the onset of chronic nephrosis in the rat<sup>4</sup>, as well as slowing the ageing process.

### Small $p\text{CO}_2$ Change and Neuronal Synaptic Activation

ALTHOUGH the effects of pharmacological and biochemical substances on synaptic activation have been extensively investigated, the influence of  $p\text{CO}_2$  has received little or no attention<sup>1</sup>. It had been shown previously<sup>2</sup> that large changes in  $p\text{CO}_2$  and  $p\text{O}_2$  altered synaptic activation, and the purpose of the present investigation was to examine quantitatively the effect of small changes in  $p\text{CO}_2$ . Since the impaled mammalian neurone is extremely fragile, the first investigations, lasting for several hours, were performed on a sturdier preparation—the identifiable giant neurones of *Aplysia fasciata*.

The visceral ganglia of 16 *Aplysia fasciata* were excised together with their nerves. As previously described<sup>2</sup> the preparation was investigated in a 2-ml. 'Lucite' cuvette located in a thermostated cylindrical chamber. The cuvette was filled with sea water and the nerves were mounted on silver chloride-silver hooks connected to a Grass stimulator. Glass micro-electrodes were inserted into selected nerve cells and, when the preparation was complete, the chamber was covered with a glass plate. Lateral apertures were used for the introduction of micro-electrodes and the admission of various gas mixtures so that the chamber could be successively filled with room air or with 5 per cent  $\text{CO}_2$  in air. Gas flow was regulated by a calibrated flow meter.

The pH and  $p\text{CO}_2$  in the blood of *Aplysia* were determined so that the same levels could be duplicated *in vitro* in the sea water surrounding the ganglion cells. A few seconds after the mollusc had been cut open, samples of blood were taken anaerobically with a tuberculin syringe from the largest vessel leading into the heart. The  $p\text{CO}_2$ ,

Fig. 1. Variation with age in the daily urinary excretion of protein nitrogen (mean  $\pm$  S.E.) in 6 male rats hypophysectomized at 50 days of age (broken line) and 23 controls (continuous line).

H and  $pO_2$  were analysed directly by means of a micro-electrode assembly, and the values obtained ranged between 2.5 and 4.3 mm mercury for  $pCO_2$ , while pH ranged from 7.53 to 7.83 and  $pO_2$  from 8 to 39 mm mercury. The pH,  $pCO_2$  and  $pO_2$  of the water in the cuvette were then measured during the admission of two gas mixtures (room air and 5 per cent  $CO_2$  in air). Every 30 sec, samples were taken from the cuvette under conditions of constant gas flow and when the ganglion was not in place to avoid any mechanical stimulation of the nerve cells). When gas mixtures were changed from room air to 5 per cent  $CO_2$  in air,  $pCO_2$  increased at a constant rate during the first 2 min (1.8 mm mercury every 30 sec); and the  $CO_2$  levels in the water of the cuvette during the experiment were close to those observed in the living animal (2–5 mm mercury). In several instances samples of sea water were taken with the ganglion in place and after significant alterations of synaptic potentials had been observed. Changes in  $pCO_2$  recorded at that time were similar to those observed previously.

Neurons, initially at rest and giving only excitatory post-synaptic potentials when orthodromically activated, were especially examined. After the micro-electrode had been inserted the ganglion was kept undisturbed for 10 min in order to obtain a control reference state. The leurogenital nerve was then stimulated at a frequency of 1 per sec and with an intensity sufficient to elicit on the soma only excitatory post-synaptic potentials. The amplitude of the excitatory post-synaptic potentials was set at a level higher than 10 mV because under such conditions marked local somatic responses are present. The substitution of room air with 5 per cent  $CO_2$  in the air in the chamber depolarized the soma very slightly and in 10 sec promoted the local somatic response to a pike. Fifty sec after 5 per cent  $CO_2$  had been introduced into the chamber all excitatory post-synaptic potentials elicited spikes indicating that synaptic excitability of the soma had been significantly increased. At the same time,  $pCO_2$  in the surrounding sea water had increased from 0 to 3 mm mercury, pH had dropped from 8.02 to 7.73 and  $pO_2$  had not changed.

After the 5 per cent  $CO_2$  mixture was discontinued and room air re-introduced into the chamber, there was a reversal of the described effects and only excitatory post-synaptic potentials were recorded as  $pCO_2$  returned to control levels. Fig. 1 illustrates the alteration in synaptic activity produced by a  $pCO_2$  change of from 0 to 3 mm mercury in the fluid surrounding the ganglion in a giant 1 neurone.

In conclusion, these observations suggest that small changes in  $pCO_2$  (1–3 mm mercury) affect the instantaneous excitability of the soma and thus the efficiency of its excitatory synaptic activation. Such changes in  $pCO_2$  occur spontaneously in most aerobic species and

could, therefore, markedly contribute to basic neuronal regulations.

## PHARMACOLOGY

### A Sensitive Assay for Inhibitory Agents of Pleuropneumonia-like Organisms

RAPID methods of measuring the potential inhibition of pleuropneumonia-like organisms (PPLO) by various agents have been evolving slowly. The phenol red serial dilution broth test has been extensively used even though certain mycoplasmas do not grow well in the broth and do not produce sufficient acid to create a sharp end-point. Griffith and Black have recently devised a haemolysis-blocking test system for comparing the activities of various antimicrobial agents against *Mycoplasma pneumoniae* (Eaton agent)<sup>1</sup>. This test and similar plate tests are relatively slow, requiring 3–7 days for completion. We have attempted at this laboratory to alter the phenol red tube dilution test by various manipulations of the dye and the inoculation procedures. We have found that resazurin is preferable to phenol red, 2,3,5-triphenyltetrazolium chloride, or 2,6-dichlorophenolindophenol dyes. The test system we chose may prove to be of use in other laboratories involved in investigations of PPLO inhibition. It is a simple tube dilution sequence that gives results within 18–24 h for most PPLO and in 30–36 h for *M. pneumoniae*. This system could most likely be shortened even further by inoculum variation. For most purposes, however, it is sufficiently rapid.

The mycoplasmas were grown in Difco phenol red maltose broth with the addition of 1.5 per cent PPLO serum fraction (Difco) and 0.025 per cent thallium acetate. Alternatively, Difco PPLO broth without crystal violet and with the aforementioned additions could also be used. The inoculum was incubated at 37° C for 18–24 h and 0.05 ml. used to inoculate 2.0 ml. test medium. Difco PPLO broth, as prepared for the inoculum, was used for the tube dilution test. Resazurin was added after separate sterilization so that the final dye concentration was 0.002 per cent. (The PPLO serum fraction was also separately sterilized.) 2.0 ml. quantities of the test medium were then transferred to a number of small blood tubes. Using the normal serial tube dilution technique, the inhibition end-point was determined as the first tube containing non-reduced resazurin. Positive and negative controls were always included for direct colour comparison. The test was incubated at 37° C for 18–24 h before reading.

When the test PPLO was *M. pneumoniae*, the inoculum was grown on Difco PPLO broth, as described by Chanock *et al.*<sup>2</sup>, and only half as much resazurin was included in the test medium. The inoculum for the test was concentrated by centrifugation and the pellet obtained resuspended in a quarter of the original volume of broth. The Chanock modified Difco PPLO broth test medium was inoculated with 0.2 ml. of this 1:4 concentrated cell suspension. The tubes could be read after 30–36 h.

Fig. 1. Giant A-type nerve cell in the visceral ganglion of *Aplysia fasciata*, orthodromically activated by brief stimuli (1 per sec) of constant intensity to the afferent nerve fibres; temp., 26° C. A, In the presence of air, only local somatic responses were elicited superimposed on the excitatory post-synaptic potentials. ( $pCO_2$  of sea water 0.02 mm mercury (calculated); pH 8.07;  $pO_2$  89 mm mercury.) B, Thirty sec after admission of 5 per cent  $CO_2$  in air, spikes were elicited on the excitatory post-synaptic potentials. ( $pCO_2$  of sea water < 3 mm mercury; pH 7.73;  $pO_2$  88 mm mercury.) C, Fifty sec after readmission of air, there was recovery to the initial excitability level. Again, only somatic local responses followed the excitatory post-synaptic potentials. ( $pCO_2$  of sea water 0.02 mm mercury (calculated); pH 8.00;  $pO_2$  92 mm mercury)

\* S cultures are isolates from the nasal passages of pigs, 699 is *M. gallisepticum*, and 698 is a bovine isolate.

Table 1 summarizes some of the results obtained when various antibiotics were compared to show their relative effectiveness against mycoplasmas. Obviously, the FH strain of *M. pneumoniae* was fairly sensitive to the action of the antibiotics.

The relative activity of erythromycin against *M. pneumoniae* is in agreement with the results reported by other research workers<sup>1</sup>.

Investigations are being continued using other methods so that a very rapid test, for example, 2-4 h, may be developed. Adaptation of these dye methods may assist diagnosis—as was recently suggested by Kraybill and Crawford<sup>2</sup>.

### Propoxate (R7464): a New Potent Anaesthetic Agent in Cold-blooded Vertebrates

PROPOXATE is the proposed generic name for *dl*-1-(1-phenyl-ethyl)-5-(propoxy-carbonyl)-imidazole HCl. It is a member of a new series of 1-substituted imidazole-5-carboxylic acid esters (Fig. 1). The prototype of this series, Etimidate (proposed generic name for R7405), is an extremely potent, rapid and short-acting hypnotic agent in a variety of animal species<sup>1</sup>. Propoxate (R7464) is a potent, polyvalent and safe anaesthetic in cold-blooded vertebrates and is very soluble in fresh and salt water. Compared with 'Tricaine' (methanesulphonate of meta-amino-benzoic acid ethylester, MS222) it is about 100 times more potent, the active concentration ranging from 0.5 to 10 p.p.m. and from 50 to 1,000 p.p.m. for R7464 and MS222 respectively.

Experiments with goldfish have been carried out in 101 aerated aquaria kept at  $19^\circ \pm 2^\circ \text{C}$ . Concentrations of R7464: 1/16, 1/4, 1, 4, 16 and 64 p.p.m., were tested at various immersion times, 1/64, 1/16, 1/4, 1, 4 and 16 h. Recovery from anaesthesia was effected by transferring the fish into clean aquaria containing aerated tap water.

Our observations have led us to assign, rather arbitrarily, the following four stages of anaesthesia: stage I, increase of respiratory movements, followed rapidly by a decrease in activity and respiration; stage II, loss of equilibrium. At this point the respiratory rate is quite slow but responses to strong vibrational stimuli persist;

		R	R'
R7405	ETIMIDATE	CH <sub>3</sub>	C <sub>2</sub> H <sub>5</sub>
R7464	PROPOXATE	CH <sub>3</sub>	nC <sub>3</sub> H <sub>7</sub>

Fig. 1

stage III, loss of righting reflex. The fish lie on the bottom of the aquarium, respiration is superficial and irregular and they do not respond to manipulation; stage IV, respiratory arrest. This stage can be maintained for a limited period of time, without fatalities occurring.

Phases resembling those of induction of anaesthesia were observed during the recovery period, but their quantitative delineation was much more difficult. Our observations are given in Table 1.

		Induction of anaesthesia, mean values 6 animals minutes' or seconds"				Recovery from anaesthesia, approx. values minutes' or hours h				Safe immersion time (h)
R7464	Im-mersion time	I	II	III	IV	IV	III	II	I

I, II, III, IV: stages of anaesthesia.

The degree of anaesthesia obtained in goldfish with R7464 is closely related to the concentration used, and various and selected depths of anaesthesia can be induced with atoxic concentrations. A slight, long-lasting tranquillization, resulting in a loss of reactivity and a decreased oxygen consumption, useful for transport, can be obtained with concentrations up to 1/4 p.p.m. A somewhat deeper level of anaesthesia inducing loss of righting reflex is obtained with 1 and 4 p.p.m. At this depth routine biological investigations can be easily performed and goldfish can be removed from the water for several hours without harmful effects, the only precaution necessary being to enclose them in moist paper. The two highest concentrations shown lead rapidly to complete respiratory arrest which can be sustained for a limited period without harmful effects—1 h for 16 and 1/4 h for 64 p.p.m.

The recovery time from anaesthesia depends on the concentration and on the duration of immersion; furthermore, great individual differences in fish may occur. As a general rule, however, disregarding the duration of immersion, it may be said that the shorter the induction time of anaesthesia, the longer the recovery, and vice versa.

Similar effects to those in goldfish were obtained in unfish with 1 and 4 p.p.m. In rainbow trout and in eafish 1/4 p.p.m. was still effective and induced stage II. In young salmon 2 p.p.m. led rapidly to loss of righting reflex, and laboratory experiments performed with *Lambusia* were very promising<sup>2</sup>.

In frogs, 2 p.p.m. paralysed the hind legs after an immersion period of 30 min; 16 p.p.m. produced loss of fighting symptoms within 10 min.

Immersion of adult species of salamanders in 4 p.p.m. or 15, 30 and 60 min was carried out without fatalities; stages II and III were easily obtained after 5 and 20 min of immersion. Allowed to recover in an empty aquarium, all animals became normal after 6 h.

### Effect of Reserpine on Atrial and Ventricular Rates in Atrial Fibrillation in Man

INVESTIGATIONS into the intrinsic rhythmicity of normal cardiac pacemakers suggest that the catecholamine content of the myocardium is an important determinant of their activity<sup>1</sup>. Reserpine depletes stores of catecholamines; in the dog heart-lung preparation after initial acceleration it slows the sinus rate<sup>2</sup>, and in the dog heart *in situ* with heart block it markedly slows the ventricular pacemaker<sup>1</sup>. In man reserpine slows the normal heart<sup>3</sup>, but since the sinus node is under extra-cardiac control this observation provides no basis for speculation concerning the mechanism of reserpine effects on the cardiac pacemaker.

Atrial fibrillation is a special circumstance in which a rapid ectopic pacemaker is relatively independent of extracardiac autonomic control. In atrial fibrillation in man, reserpine slows the ventricular rate<sup>4</sup>, but its effect on the atrial rate has not been reported. The slowing of the ventricular rate does not mean that there is necessarily a corresponding change in atrial rate, for in atrial fibrillation where the ventricle responds to atrial impulses, changes in atrial rate often result in reciprocal changes in ventricular rate, for example, after quinidine the atrial rate falls and the ventricular rate rises. In addition, ventricular rate may change as a result of effects on AV conduction. An acceleration of ventricular slowing by atropine in one patient as reported by Marangoni and Cavusoglu<sup>4</sup> does not establish increase of vagal tone by reserpine since atropine could accelerate the ventricle if reserpine had not been given.

After a two-week control period, 7 patients with atrial fibrillation, suffering from mental disease but not in congestive failure, were given reserpine in daily oral doses of 2.0 mg for one week, and 3.0 mg for the week following, after which the reserpine was withdrawn. There were no other changes in medication during the investigation period. The atrial rates were counted according to the method of Gold *et al.*<sup>5</sup> in 1-min electrocardiographic strips (sternal lead), before the administration of reserpine, twice weekly during treatment with reserpine and at the end of each week after withdrawal. Ventricular rates were determined from the same strips of electrocardiogram.

The averages of the counts were plotted. The curves (Fig. 1) indicate that the ventricular rate fell after the first week of treatment, continued below the control during the entire treatment period (but did not fall further when the dose was raised from 2.0 mg to 3.0 mg per day, indicating that the former was a ceiling dose)

Fig. 1. Atrial and ventricular rates in seven patients with atrial fibrillation receiving reserpine. —, Ventricular rate (100 per cent = 85.7/min); ---, atrial rate (100 per cent = 40.7/min)

and rose after the first week of withdrawal, returning to control at the end of the second week. The atrial rate was not changed by the reserpine. The average rates after reserpine were paired with control rates in each case and examined by the sign test. The *P* value for the atrial slowing compared with control was 0.31 during treatment and 0.4 after treatment. The *P* value for ventricular slowing was 0.005 during treatment and 0.39 after withdrawal. Our findings are diametrically opposed to those of Arora<sup>6</sup>, who observed atrial slowing but no ventricular change after reserpine in atrial fibrillation induced by aconite in the dog heart *in situ*.

Since in our cases there was no change in atrial rate, there could have been no significant effect of catecholamine depletion on the ectopic mechanism, and since all ventricular beats were responses to atrial impulses, the only simple and reasonable explanation for the ventricular slowing is depression of AV conduction by reserpine. Nothing in this experiment bears on the mechanism of the effect; there are the possibilities of unopposed vagal activity as a consequence of catecholamine depletion, a central action to increase vagal tone, and, as already suggested by Innes, Krayer and Waud<sup>7</sup> on the basis of observations in the dog heart-lung preparation, of a direct depressant effect on AV conduction.

### HAEMATOLOGY

#### Polypeptide Chains of Buffalo Haemoglobins

THAT many breeds of cattle exhibit polymorphism involving two haemoglobin types is now well established<sup>1</sup>. On the other hand, buffalo haemoglobin seems to be monomorphic in that all buffaloes examined possess two major haemoglobin components<sup>2,3</sup>. Bovine haemoglobins have been fairly thoroughly characterized<sup>1</sup> and it has been suggested that the two bovine haemoglobins may contain one polypeptide chain in common<sup>4</sup>.

This report describes the isolation of the two buffalo haemoglobins through carboxymethylcellulose columns, followed by evaluation of these pigments by means of resolution of the globins into their sub-units by paper electrophoresis in 6 M urea and by peptide pattern analysis of the globins and the separated polypeptide chains.

Haemolysates were prepared according to Drabkin<sup>2</sup>. The preliminary survey of the haemoglobins was carried out by paper electrophoresis in barbitone-HCl buffer, pH 8.6 ( $I = 0.05$ ). For separation into two components, the cyanomet forms of the buffalo haemoglobins were subjected to carboxymethylcellulose chromatography by a method modified from that of Huisman *et al.*<sup>3</sup>. The cellulose exchanger was prepared<sup>7</sup> from cellulose powder No. 123 (Carl Schleicher and Schüll) and was finally equilibrated with 0.01 M phosphate buffer, pH 6.0. The fast-moving component (higher anodic mobility at pH 8.6, referred to as 'buffalo-Hb-fast') was eluted by using phosphate buffer of pH 6.9, and the slower component ('buffalo-Hb-slow') at pH 7.4. The haemoglobins were dialysed prior to concentration by pervaporation. Globins were prepared according to Anson and Mirsky<sup>8</sup>. The globins were resolved by paper electrophoresis, run in 6 M urea with pyridine-acetic acid buffer of pH 6.8 according to the method of Take<sup>9</sup>, who resolved bovine globins into two sub-units moving towards the cathode, the faster

Fig. 2. Electrophoretic resolution of the globins of buffalo-Hb-fast and buffalo-Hb-slow in 6 M urea with pyridine-acetic acid buffer at pH 6.8

Fig. 3a. Tracings of the fingerprints of tryptic digests of the globins of buffalo-Hb-fast and buffalo-Hb-slow. Electrophoretic buffer: Michl's buffer pH 6.4. Chromatographic solvent: butanol-pyridine-acetic acid-water (30:20:6:24)

Fig. 3b. Photographic representation of the fingerprints of tryptic digests of the  $\alpha$ -chains of buffalo-Hb-fast and buffalo-Hb-slow. Electrophoretic buffer: Michl's buffer pH 6.4. Chromatographic solvent: butanol-pyridine-acetic acid-water (30:20:6:24)

component being found to correspond to the Val-Leu-chain and the slower to the Met-chain. The two polypeptide chains of buffalo globins were isolated according to the trichloroacetic acid precipitation method, as applied to bovine globins<sup>10</sup>. The purity of the chains was checked by paper electrophoresis in 6 M urea at pH 6.8. While the  $\alpha$ -chains (higher cathodic mobility) were pure, the  $\beta$ -chains (lower cathodic mobility) showed traces of the faster component. Tryptic peptides and finger-prints were prepared in the usual manner<sup>11</sup> with butanol-pyridine-acetic acid-water as the chromatographic solvent<sup>12</sup>.

The 38 samples of buffalo haemolysates examined showed two haemoglobin components in each, as against cow haemolysates (Gir breed) where polymorphism involving two haemoglobin components was observed (Fig. 1). The examination of globins of the buffalo-Hb-fast and buffalo-Hb-slow for their sub-units by electrophoresis in 6 M urea at pH 6.8, indicated that mobilities of the  $\alpha$ -chains of the two buffalo haemoglobins were different whereas that of the  $\beta$ -chains appeared similar (Fig. 2). This is in contrast to the globins of bovine Hb-A (lower anodic mobility at pH 8.6) and bovine Hb-B, which seem to share  $\alpha$ -chain in common while  $\beta$ -chains are different (see Fig. 2). The fingerprints of the globins and of the separated polypeptide chains of buffalo-Hb-fast and buffalo-Hb-slow indicated that the  $\alpha$ -chains of these two pigments (higher cathodic mobility at pH 6.8 and of comparable mobility to the Val-Leu-chain of the bovine globin) differ in three peptide spots, one involving tryptophan (Fig. 3a and 3b). The  $\beta$ -chains (of comparable mobility to the Met-chain of the bovine globin), however, did not indicate differences in their peptide patterns.

Comparison of the tryptic peptide pattern and characterization of individual polypeptide chain of bovine-Hb-A, ovine-Hb-B, buffalo-Hb-slow and buffalo-Hb-fast is being carried out.

### <sup>32</sup>P-labelling of Nucleotides from a Soluble Erythrocyte-membrane Fraction devoid of Haemoglobin

In a previous paper<sup>1</sup>, the incorporation of radioactive organic phosphate into human red-cell ghosts was investigated in great detail. About 30 labelled phosphopeptides could be isolated, and their amino-acid patterns were determined. The rate of incorporation and its pH-dependence were also estimated. It was also shown<sup>2</sup> that the <sup>32</sup>P-incorporating membrane factor could be extracted and purified, and at least some part of the phospholipids also seemed to be metabolically active, since labelled phosphorylethanolamine and phosphorylcholine could be isolated. In addition, it was briefly mentioned that labelled trichloroacetic acid (TCA)-soluble inosine triphosphate (ATP) seemed to be formed in the labelling process. In the TCA-insoluble material, labelled ultra-violet-absorbing substances were also present.

Post *et al.*<sup>3</sup> have recently demonstrated a possible linkage between ATPase activity in the red-cell membrane and active transport of sodium, and Hoffman<sup>4</sup> has also shown that ATP might provide energy necessary for the sodium transport mechanism. Earlier investigators, including Hurley<sup>5</sup>, Gerlach *et al.*<sup>6</sup>, Tatibana *et al.*<sup>7</sup>, Bartlett<sup>8</sup> and Parsky *et al.*<sup>9</sup>, have all found that ATP in the erythrocyte content seems to be the primary acceptor when red cells are incubated with <sup>32</sup>P. Schauer and Hillman<sup>10</sup>

have found some evidence of the presence in the red-cell membrane of an ultra-violet-absorbing, acid-labile compound which they believed might be engaged in the phosphorus transport. Another possible intermediate in the process of <sup>32</sup>P transport across the membrane is ATP formed in the membrane itself. Some data have been found which support this hypothesis.

A *tris*-glycylglycine extract of human red-cell ghosts washed with water was prepared as previously described<sup>2</sup>. After isoelectric precipitation at pH 6.0 and removal of the precipitate, the solution was filtered through 'Sephadex G-200' columns. In each preparation, material from 600–700 ml. of packed red cells was used. The colourless lipoprotein fraction first eluted from the 'Sephadex' columns was used in the subsequent experiments. Incubation with <sup>32</sup>P (0.1 mc./ml.) was carried out at about 20° C for 4 h in the presence of 1 × 10<sup>-4</sup> M unlabelled Na<sub>2</sub>HPO<sub>4</sub>. Excess of free <sup>32</sup>P was removed by filtration through 'Sephadex G-25' medium-size columns.

TCA-soluble nucleotides from human erythrocyte material were prepared in the following way. Haemolysis of washed red cells was carried out by addition of 9 volumes of distilled water. The pH was adjusted to 6.0 by a flow of CO<sub>2</sub>. After storage overnight at 4° C in the cold room, the ghosts (usually from about 600 ml. of packed red cells) were removed by centrifugation in a refrigerated Stock centrifuge. The haemolysate was concentrated by evaporation *in vacuo* at 18° C to about one-tenth of the original volume. Haemoglobin and other proteins were precipitated by addition of concentrated cold TCA to a final concentration of 10 per cent. The precipitate was removed by centrifugation, and excess TCA was extracted by shaking 4 or 5 times with an equal volume of ethyl ether. The pH was adjusted to 5.5 with 5 N NaOH, and the volume of the solution to 100 ml. When not immediately used, the solution was stored in a cold room at -16° C.

The labelled <sup>32</sup>P-incorporating lipoprotein complex from about 600 ml. of packed red cells was incubated for about 30 sec with TCA-soluble nucleotides from the content of the same volume of cells. The protein was precipitated by addition of TCA. TCA was removed by extraction with ethyl ether as usual, and the solution was concentrated and run through a 'Dowex-1' (2 per cent DVB) column, mainly according to Hurlbert *et al.*<sup>11,12</sup>. The labelled nucleotide fractions were either directly analysed for phosphorus<sup>13</sup>, ribose<sup>14</sup> and base constituents<sup>15</sup> or, after preliminary purification by paper ionophoresis, scanning of the electropherograms and elution of labelled spots with ultra-violet absorbancy.

In this way, it was found that the two largest labelled ultra-violet-absorbing peaks consisted of ATP and guanosine triphosphate (GTP), respectively. Smaller

Fig. 1. Acid-soluble nucleotides from an incubation mixture of the <sup>32</sup>P-incorporating lipoprotein complex extracted from ghosts of 600 ml. of human red cells and the TCA soluble nucleotides from the content of the same volume of cells. Incubation with <sup>32</sup>P (0.1 mc./ml.) for 30 sec. The nucleotides were separated by gradient elution with the reservoir content changed in the tubes numbered as follows: 70, 1 N formic acid; 180, 4 N formic acid; 300, 0.2 M ammonium formate + 4 N formic acid; 480, 0.4 M ammonium formate + 4 N formic acid. Column dimensions 65 × 9.2 ml. Mixing volume 600 ml. and tube volumes about 20 ml. The continuous line represents radioactivity, the broken line light absorption at 260 mμ. Registration procedure as in ref. 17.

amounts of labelled adenosine diphosphate (ADP) and guanosine diphosphate (GDP) were also observed. Further on, a large labelled peak was eluted after GTP. It contained adenosine, and could possibly be identical with the ATP-2,3-diphosphoglycerate complex described by Hashimoto and Yoshikawa<sup>16</sup>. Quite unexpectedly, a large quantity of <sup>32</sup>P was eluted from the 'Dowex-1' column, despite preliminary separation by filtration on the 'Sephadex G-25' column. The reason for the appearance of this <sup>32</sup>P peak is not clear. When the labelled lipoprotein complex was precipitated directly by TCA, without previous incubation with TCA-soluble nucleotides from the red-cell haemolysate, the same labelling pattern of slightly ultra-violet-absorbing peaks appeared on the 'Dowex-1' column chromatogram<sup>17</sup>. The small amounts of material available did not permit any closer identification. Another interesting observation was made when the lipoprotein complex had been rapidly frozen to -186° C in liquid nitrogen<sup>2</sup> before incubation with <sup>32</sup>P. When the material was rapidly thawed and incubated with <sup>32</sup>P, and mixed with nucleotides as described here, it was not possible to observe any labelled nucleotide peaks in the eluate from the 'Dowex-1' column chromatography.

One of the reasons why the mechanism of ATP formation in red-cell ghosts has been difficult to investigate is the strong ATPase activity, strongly fixed to the insoluble membrane residues left after exhaustive extraction with *tris*-glycylglycine buffer in the Spinco ultracentrifuge, whereas the lipoprotein complex is devoid of such enzymatic activity.

## IMMUNOLOGY

### Vitamin A-induced Rejection of Autografts and Homografts

HYPERVITAMINOSIS A has been shown to suppress delayed hypersensitivity reactions in the guinea-pig<sup>1</sup>. Large doses of vitamin A were also shown to cause the release of lysosomal proteolytic enzymes, both *in vitro* and *in vivo*<sup>2</sup>. In an earlier publication we suggested that proteolytic processes may be of importance in graft rejection<sup>3</sup>. In the present investigation the effects of hypervitaminosis A on transplantation of auto- and homografts in rabbits are described.

Local wild rabbits of 2.5–3 kg were used. Autografts were made on 10 rabbits by grafting pieces of full-thickness abdominal skin, 2 cm × 2 cm in area, to the rabbit's own back. Homografts of identical size were exchanged

between 14 rabbits grouped in pairs. Vitamin A palmitate, 1,700,000 units/kg, was injected intraperitoneally every second day, starting on the day of the skin grafting. As controls, autografts were performed on 10 rabbits and homografts were exchanged between five pairs of rabbits not receiving vitamin A.

Autografts in untreated rabbits were consistently successful and after 12–14 days showed evidence of permanent take. Homografts in the control animals were constantly rejected, the longest survival being 13 days.

Autografts in vitamin A-treated rabbits already appeared pale on the 6th day, at the time of removal of the compressive bandages. Between the 10th and 15th post-operative day the grafted skin was detached from the graft bed. The detachment occurred either spontaneously or at the slightest touch. The graft bed was slightly bleeding at the time of detachment and the grafted skin was whitish-grey in colour and appeared non-viable.

The fate of the homografts in the vitamin A-treated rabbits was similar to that of the autografts. On the 7th post-operative day the homografts appeared non-viable. They lost their attachment to the bed between the 7th and 9th day. In spite of the spontaneous separation from the graft bed, no haematomata, serous accumulations or pus were found beneath the graft.

Serial biopsies taken from the grafts of the vitamin A-treated rabbits showed early epidermal and dermal degenerative changes and/or necrosis despite an almost normal graft bed in which the only unusual finding was a peculiar paucity of blood vessels. The homografts of vitamin A-treated animals showed a mild round cell infiltration only. The similar fate of both auto- and homografts in the vitamin A-treated rabbits excludes the possibility that an immune mechanism is involved in this 'graft rejection'.

Unsuccessful autografts have been reported in sublethally irradiated rats, possibly due to interference with the vascularization of the graft<sup>4</sup>. Assuming that the rejection of both auto- and homo-grafts in the vitamin A-treated rabbits was also due to interference with the vascularization of the graft, the effects of vitamin A on neovascularization were studied. In these experiments, an account of which is being prepared, the effect of hypervitaminosis A on vascular neoformation in the rabbit cornea was examined. It was found that, in rabbits which received injections of 0.1 N HCl intracorneally, vitamin A palmitate administration completely prevented neo-vascularization of the cornea<sup>5</sup>. The mode of action of vitamin A in preventing vascular neoformation and consequent 'graft rejection' is not yet clear.

This investigation was aided by grant NB 2018 National Institutes of Health, U.S. Public Health Service Bethesda.

## PATHOLOGY

## Staphylococcal Interference in Infections in Embryonated Eggs

THE protection afforded by infection with avirulent virus against subsequent challenge with a second lethal virus<sup>1</sup> has led to the demonstration of interferon production by infected cells *in vitro* and *in vivo*<sup>2,3</sup>. Despite clinical evidence of the importance of bacterial interference, and experimental demonstration that avirulent staphylococci are capable of inhibiting nasal colonization with virulent staphylococci<sup>4</sup>, bacterial interference has not been extensively investigated in experimental models. Investigations of experimental staphylococcal infections in embryonated eggs have demonstrated that infection with strains of staphylococci that are not virulent for eggs affords significant protection against subsequent challenge with virulent staphylococci.

Ten-day-old embryonated eggs were injected with from 10 to 100 colony forming units (c.f.u.) of avirulent coagulase-negative *Staphylococcus epidermidis* or coagulase-positive *Staphylococcus aureus* intra-allantoically, and one-half of each group were challenged with 10–100 c.f.u. of virulent *Staphylococcus aureus* 48 h later. The remainder of the eggs infected with avirulent staphylococci served as controls and were injected with 0.1 ml. of saline two days later. Virulence controls received 0.1 ml. of saline on day 10 followed by intra-allantoic injection of 0.1 ml. of a broth culture of virulent *S. aureus*, diluted to contain 10–100 c.f.u., 48 h later. Eggs were candled daily to determine viability. Table 1 demonstrates the fatality rates in each of these experimental groups. Infection with either *S. epidermidis* or virulent *S. aureus*, lines 1 and 4, produced fatality rates ranging from 18 to 20 per cent. The fatality rates observed after saline injection followed by challenge with virulent *S. aureus*, lines 3 and 6, approximated 80 per cent. Prior infection with avirulent strains, lines 2 and 5, afforded significant protection against subsequent challenge with virulent staphylococci (lines 2 and 5 versus lines 3 and 6:  $\chi^2 = 40$ ;  $P < 0.001$ ). The fatality rates of eggs infected with avirulent staphylococci followed by virulent staphylococci (28–30 per cent) did not differ materially from those observed in eggs infected with virulent strains alone. Similar protection was afforded using four other strains of avirulent *S. epidermidis* and *S. aureus* for the initial infection. Significant protection was also observed using different challenge strains of virulent *S. aureus*. In addition, prior infection with avirulent staphylococci afforded significant protection against challenge with egg virulent strains of *Salmonella typhimurium*, *Diplococcus pneumoniae* and *Streptococcus pyogenes*.

The mechanism of protection could not be explained on the basis of alterations in the chorio-allantoic fluid or exhaustion of nutrient materials essential for the growth of the challenge strain. Allantoic fluid taken from uninfected controls and from eggs infected with avirulent

staphylococci, sterilized by filtration through a Millipore filter (0.45 $\mu$ ), were inoculated with the challenge strain of *S. aureus* for determination of growth curves. The growth of virulent *S. aureus* was identical in both types of allantoic fluid, indicating that previously infected allantoic fluid was capable of supporting optimal growth of the challenge strain and that no filterable substance capable of inhibiting the extra-cellular growth of the challenge strain was produced in the allantoic fluid as a result of prior infection. *In vivo* growth of the challenge strain in the presence of active infection with a non-virulent strain varied with different strains. One strain of virulent staphylococci attained similar population densities ( $\pm 10^8$  bacteria/ml.) in the allantoic fluid of infected eggs to those observed in uninfected eggs. A second challenge strain, however, failed to multiply well in the presence of active infection with an avirulent strain.

The protective effect of active bacterial infection with avirulent staphylococci against super-infection in these experimental infections appears to be well established from these investigations. The results support the clinical observations of the protective effect of the normal body flora. In addition, the findings closely parallel the experimental demonstration of the ability of avirulent staphylococci to inhibit nasal colonization and staphylococcal infection in infants<sup>4</sup>. The mechanism of protection in this experimental system remains undefined and the subject of further investigation. Several features suggest that bacterial interference in this system reflects a phenomenon different from that of viral interference and interferon production.

## Non-specificity of Thioflavine-T as an Amyloid Stain

It has been claimed by several workers<sup>1,2</sup> that thioflavine-T is more sensitive and consistent than congo red and methyl violet as an amyloid stain. Vassar and Culling<sup>3</sup> found no substances which gave false positive reactions apart from myeloma casts and keratin, which do not present a diagnostic problem. McAlpine, Radcliffe and Friedman<sup>4</sup> support these findings but point out that no extensive control investigation has been carried out on 'hyaline' substances with thioflavine-T.

The fluorescent technique described by Culling<sup>5</sup> was therefore adopted as a routine staining method for amyloid at the Royal Free Hospital. It was then discovered that there was often a marked variation in the intensity of

fluorescence from case to case. While most of the cases of amyloidosis were strongly positive and gave a brilliant greenish yellow fluorescence, a few gave only a weak fluorescence. This, however, was interpreted as positive until a negative control, a section of kidney from a case of polyarteritis nodosa, was found to be more strongly positive than some cases of known amyloidosis. Possible sources of false positive results were therefore sought. Formalin-fixed tissues were used and sections were examined unstained or stained with thioflavine-T, congo red and methyl violet. The results obtained in six cases of amyloidosis are shown in Table 1.

Sections from six kidneys and two spleens from cases with diseases associated with 'hyaline' lesions, but not amyloidosis, were similarly investigated. Sections of rat

heart muscle from a case of experimental hypertension together with two sections of fibrin clots were also examined. The results are shown in Table 2.

It will be noticed that the genuine cases of amyloidosis did not show autofluorescence except in one doubtful case. On the other hand, out of eleven false positives, seven displayed some degree of autofluorescence. It is known that formalin fixation enhances the autofluorescence of most tissue and this was particularly noticeable in 'hyaline' substances. It seems likely that this autofluorescence is only slightly affected by staining with thioflavine-T, being accentuated in some cases and somewhat quenched in others. In most cases, it came through sufficiently to result in a false positive reading.

### Phenylalanine Tolerance Test for Heterozygous Carriers of Phenylketonuria

HSIA *et al.*<sup>1</sup> found that plasma phenylalanine levels were substantially higher after the ingestion of a standard dose, based on body-weight, of this substance by parents of phenylketonuric patients than the levels found in a comparable (age, sex, etc.) normal control group. The same observation was made by Berry, Sutherland and Guest<sup>2</sup>. Hsia *et al.* interpreted their results as indicating that a deficiency of the enzyme responsible for phenylalanine metabolism exists in the heterozygous carriers. However, if the data of Hsia *et al.*<sup>1</sup> and Berry, Sutherland and Guest<sup>2</sup> on phenylalanine concentration as a function of time are plotted<sup>3</sup>, it will be seen that the slope of the disappearance curve is essentially the same in the test group and in the control group. The data of Berry, Sutherland and Guest<sup>2</sup> actually suggest that phenylalanine is removed more rapidly by the test group than it is by normal subjects.

Since the rate of disappearance of phenylalanine (not magnitude of plasma level) is the criterion by which enzyme activity should be assessed, the findings of both groups of workers<sup>1,2</sup> cannot be used in support of the view that an enzyme deficiency exists in the heterozygous carrier. A possible reason for the differences found in plasma levels of phenylalanine in the test and control groups is that the volume of fluid (other than blood) in which this substance becomes distributed after absorption (that

## BIOLOGY

### Nutrient Content of Rainwater in the Gambia

QUANTITIES of nutrients deposited by rainfall in the tropics have been measured by several workers. Venema<sup>1</sup>, in reviewing work on the nitrogen content of rain, showed wide variations from 2.2 to 41.7 lb./acre/year. He observed that total nitrogen is at its highest concentration when a period of drought is followed by heavy rainfall; when rainfall is small, its nitrogen content is high, and vice versa. Visser<sup>2</sup>, in Uganda, observed that the heavier the shower the more nitrate-N is precipitated, and stated that storms preceding heavy rain take a lot of dust into the atmosphere from which NO<sub>3</sub> is later washed. This is no doubt true of other nutrients as well. Jones<sup>3</sup> measured the nutrients added to the soil by a rainfall of 42 in. in northern Nigeria and recorded high values for nitrogen, phosphorus, potassium and sodium of 50.8, 3, 32.8 and 53.8 lb./acre respectively.

Rainwater was collected monthly from three agricultural stations in the Gambia in 1963 (Table 1).

Table 1. TOTAL ANNUAL INCREMENT OF NUTRIENTS (LB./ACRE)

Station	Miles from sea	Total rainfall	N	P	K	Ca	Na
Yundum	9	41.5	42.0	0.28	5.3	3.9	8.5
Joel	81	39.6	40.1	0.14	3.8	2.4	7.9
Roberti kunda	136	27.9	12.7	0.24	2.5	1.5	5.2

It is seen that, on the whole, the farther from the coast the less rainfall and the less nutrients added to the soil by the rain. Values for nitrogen at two stations were most as high as those quoted by Jones at Samaru, but those for phosphorus, potassium and sodium were very much lower, being in the region of one-tenth of those from northern Nigeria. Calcium, on the other hand, is higher than the value quoted by Jones of 0.9 lb./acre.

The climate of the Gambia has been described as Sahalo-megaleses<sup>4</sup>, with the annual rainfall falling in the period from mid-October, the most intense storms occurring at the beginning and the end of the rainy season. The long scorching dry season, coupled with almost complete lack of structure of upland sandy loam top soils, results in wind erosion at the beginning of the rains and dust blowing into the atmosphere. This is reflected in the actual concentrations of nutrients falling, represented on a monthly basis in Table 2, together with monthly rainfall values.

Table 2. MONTHLY RAINFALL VALUES AND CONCENTRATIONS OF NUTRIENTS

Station	Month	Rainfall (in.)	N p.p.m.	P p.p.m.	K p.p.m.	Ca p.p.m.	Na p.p.m.
Yundum	June	1.3	1.79	0.062	3.15	2.25	7.51
	July	12.4	7.95	0.050	0.70	1.05	0.76
	August	12.5	4.76	0.026	0.35	0.00	0.78
	September	10.9	1.46	0.008	0.45	0.00	0.55
Joel	October	4.5	2.02	0.024	0.37	0.25	0.63
	June	4.0	1.68	0.010	1.15	0.50	2.32
	July	13.0	4.82	0.018	0.40	0.35	0.78
	August	11.0	6.22	0.016	0.25	0.20	0.59
Roberti kunda	September	6.4	4.31	0.012	0.40	0.10	0.92
	October	5.2	2.24	0.022	0.35	0.20	0.62
	June	0.5	2.07	0.044	0.60	0.10	1.55
	July	7.4	1.96	0.062	0.42	0.50	0.93
	August	10.6	1.96	0.034	0.37	0.20	0.50
	September	4.2	1.68	0.030	0.40	0.10	0.48
	October	5.1	2.46	0.020	0.40	0.10	1.56

The concentration of nitrogen varies considerably with a marked drop at the station farthest from the coast. At Yundum, N concentration is highest in July, corresponding to a period of intense storms following a short drought of approximately 3 weeks after the first rains.

Concentrations of phosphorus are, as expected, very low; it has been stated<sup>5</sup> that samples of 'harmattan' dust collected in Northern Nigeria contain no P<sub>2</sub>O<sub>5</sub>, and the top soils of the Gambia savannah upland contain only small amounts of total phosphorus.

Generally speaking, values for potassium and calcium are highest at the beginning of the rains and indicate that the elements are either washed from, or fall in the form of, dust present in the atmosphere. The highest concentrations of sodium occur near the coast in the early rains and are related to an easterly trade wind carrying fine particles of salt water over the land.

Total additions of nutrients to the soil seem to have little agricultural significance except in the case of nitrogen, where monthly additions of 10-20 lb., during July and August, must play an important part in satisfying the pre-nodulation nitrogen requirements of the groundnut, the main cash crop of the country. The influence of rainfall nitrogen on subsistence cereal crops must be considerable, as all cereals show a marked response to nitrogenous fertilizers on the typical savannah soils of low nitrogen content.

### High Photosynthetic Efficiency in a Low-latitude Environment

PLANT physiologists, agronomists and plant breeders over the years have been investigating the many aspects of dry matter production and the efficiency of utilization of solar energy with the view of maximum production. The factors affecting production may be subdivided broadly into genetic, edaphic and climatic factors. Climate, the most difficult to modify, frequently limits the production potential of an area. Little has been published on the maximum growth rate of individual species in different environments together with the relevant radiation values necessary to estimate photosynthetic efficiency. Also, data of this type have been obtained mainly in the middle to high latitudes in Europe and the United States.

A growth investigation at Katherine, N.T., Australia, is of interest in this regard because of the high maximum growth rate recorded in a low-latitude environment for a rain-fed crop of bulrush millet (*Pennisetum typhoides*). The climate at Katherine (132°3' E. long.; 14°3' S. lat.; 107 m alt.) has been described<sup>1</sup> as tropical savannah with a mean annual rainfall of 926 mm, 95 per cent of which falls in the five months November to March. The growth of a field crop of bulrush millet was investigated by gathering replicated sections of the above-ground portions of a bulk crop at fortnightly intervals from January to May 1964. A peak growth rate of 54 ± 5 g m<sup>-2</sup> day<sup>-1</sup> was recorded for the period April 1-15 when insolation, measured with a Kipp solarimeter, averaged 510 cal. cm<sup>-2</sup> day<sup>-1</sup>. This represents storage as dry matter in the crop of 4.2 per cent of the total incoming radiation and 9.5 per cent of the visible component (400-700 mμ), assuming a caloric content of 4,000 cal. g<sup>-1</sup>, and assuming that the visible component is 44 per cent of the total radiation. This very high growth rate for a rain-fed crop was recorded following full light interception and floral

Table 1. PEAK GROWTH RATES, AVERAGE INSOLATION AND ESTIMATES OF EFFICIENCY OF UTILIZATION OF TOTAL AND VISIBLE RADIATION

\* Includes root weight.

initiation, at a time of active internode elongation and inflorescence development. Also associated with internode elongation was a change in leaf display and a more effective distribution of the light within the crop canopy.

Compared with some high growth rates and estimates of efficiency of utilization of solar radiation recently reported<sup>2-5</sup> (Table 1), the peak growth rate of bulrush millet exceeded that of irrigated sudan grass in California, yet occurred at a lower level of insolation, which represents a considerably higher photosynthetic efficiency. Watson<sup>5</sup> recorded the same photosynthetic efficiency for the slower growing *Beta maritima*, but this was at a much lower level of insolation, where high values for photosynthetic efficiency could be expected<sup>6</sup>. The high level of photosynthetic efficiency recorded for bulrush millet was associated with growth rates almost twice as great as *Beta maritima* and moreover took account only of the top growth, whereas the roots of *Beta maritima* were included. A high light saturation value together with a high optimum temperature (30°-35° C) for net photosynthesis in bulrush millet could account for this, enabling the crop to flourish in this low-latitude environment.

### Auxin-induced Reversal of Geotropic Response in Onion Seedlings

IN the course of an investigation concerning the germination of onion seeds and subsequent growth of seedlings in aseptic cultures, a striking and unique response to auxin was observed. In normal germination, as observed in Nature or on the basal medium (comprising Heller's minerals and 5 per cent sucrose solidified with 0.7 per cent agar), there is an intercalary elongation of the cotyledon resulting in the emergence of the root and the shoot apex. Due to a curving of the cotyledon the radicular end is carried downward and thus the seedling is established in the soil or on a synthetic nutrient medium. The free end of the cotyledon remains inserted in the seed coat and, as it elongates farther, the seed coat is lifted from the substratum (Fig. 1A).

In a nutrient medium containing auxin, however, the mode of germination is totally different. The radicle end, after its emergence from the seed, curves upward (that is, becomes negatively geotropic) instead of growing downward (Fig. 1B, C). Afterwards, rootlets appear at the tip. Concomitantly, a number of scale leaves develop at the apex resulting in the formation of an 'aerial' bulb.

High concentrations of auxins such as indolyl-3-acetic acid (IAA) inhibit the growth of seedlings, which remain

Fig. 1. Germination of seeds on basal medium (A); on basal medium containing IAA  $10^{-6}$  M (B)—note the inverted position of the seedlings; magnified view of inverted seedlings grown on basal medium containing IAA (C).

Fig. 2. Histogram showing percentage of inverted seedlings on basal medium containing different auxins and an anti-auxin—dotted bars represent the cultures grown in dark and white bars in light.

stunted. Nevertheless, the apparently negative geotropic response—in terms of percentage of inverted seedlings—is directly proportional to an increase in the concentration of auxin (log-linear to IAA between  $10^{-8}$  and  $10^{-4}$  M concentration; Fig. 2). Indolyl-3-acetic acid at  $10^{-8}$  and  $10^{-7}$  M promotes growth but the negative geotropic response is poor; at higher concentrations there is a marked response although the growth is inhibited. At  $10^{-4}$  M practically all the seedlings are inverted.

Curiously enough, if the tubes are kept in an inverted position there is no difference in the orientation of the seedlings grown on media with or without IAA. In both cases the radicular end grows away from the medium in the direction of gravity.

This response is not limited to IAA alone; other auxin like indolyl-3-butyric acid (IBA), naphthaleneacetic acid (NAA) and 2,4-dichlorophenoxyacetic acid (2,4-D) influence the growth of seedlings in a similar way although the results are variable (Fig. 2). Triiodobenzoic acid (TIBA), used at concentrations of  $10^{-6}$  and  $10^{-5}$  M, does not reverse the effect of auxins. On the contrary, when used with IAA, it augments its effect.

Besides *Allium cepa*, experiments have been performed with the seeds of *A. fistulosum*, *A. hymenorrhizum*, *A. ramosum*, *A. sphaerocephalum* and *A. tuberosum*. In each case the response to auxins is the same, but the percentage of seedlings showing inverted orientation is variable. In some species the response is less marked than in *A. cepa*; in others such as *A. tuberosum* almost all the seedlings are negatively geotropic.

The tropic response of the seedlings kept in continuous light (30–40 ft.-candles) is much weaker than of those kept in complete darkness (Fig. 2).

To the best of our knowledge the experimental results described here have not been reported earlier, even though experiments closely approaching ours have been made with other materials<sup>1-3</sup>. We are unable, at present, to explain this response in terms of the Went-Cholodny theory of geotropism or in any other way, but further work is in progress to settle this question.

We thank Prof. P. Maheshwari for his advice and Dr. L. K. Mann, Department of Vegetable Crops, Davis, California, for providing the seeds of several species of *Allium* used in this work.

### Xylem Sap Composition in Woody Plants

SAP exuded from decapitated root stumps has frequently been regarded as similar in composition to that moving in the transpiration stream<sup>1-4</sup>. This assumption is open to doubt.

During experiments on phosphorus transfer in willow I have repeatedly obtained results similar to those reported here. Rooted golden-willow cuttings (*Salix vitellina*) taken in late winter were grown in nutrient solutions containing either a normal level of phosphorus or no phosphorus. When differences in growth were apparent between the two treatments plants were transferred to a full nutrient solution containing 3 mM phosphate and sufficient <sup>32</sup>P as ortho-phosphoric acid to give an activity of 50 µc./l. At this stage stem bases were approximately 4 mm in diameter and the shoots were 2-3 ft. long with fully expanded leaves. After transfer to the radioactive solution, transpiration losses from the pots were made up frequently and plants were gathered after 1, 2 and 14 days. All leaves were removed quickly from the stems, which were then cut off at the base, and sap was extracted by Bollard's method<sup>5</sup>; this usually extracted 1-2 ml. of clear sap. A measured portion of this was spotted on to filter paper and the radioactivity was assayed, using an end-window Geiger-Müller tube. As soon as the stem was removed a glass tube was connected to the root stump and the first 0.5 ml. of the exuded sap was collected. This took only a few minutes—always less than half an hour. An aliquot of this sap was also spotted on to filter paper and assayed, as was an aliquot of the ambient solution taken when the plants were gathered. Results are given in Table 1.

I am not aware of any evidence showing that a substantial gradient of mineral concentration normally exists from bottom to top of the xylem column in transpiring plants. A more probable explanation of the results recorded in Table 1 is that when a stem is cut off there is a sudden and immense change in the phosphorus content of the xylem sap in the stump. This change could be due to the secretion of phosphorus compounds by root cells into the xylem vessels<sup>6</sup>. Some evidence for this interpretation was obtained from chromatograms made from sap samples using a 3° butanol/picric acid/water solvent, in that stem sap contained only inorganic <sup>32</sup>P, while in root

Fig. 1. Radiochromatogram of root and stem sap. In 3° butanol/picric acid/water solvent. The low  $R_F$  values in root sap are due to high electrolyte concentration in this material. —, Root exuded sap; — — —, stem xylem sap; — · — · —, standard  $H_2P^*O_4$ .

sap substantial peaks of activity were frequently found running behind the inorganic <sup>32</sup>P (Fig. 1).

The phosphorus composition of exuded root sap therefore has little connexion with that of the transpiration stream as extracted by Bollard's method.

### Spider Genus *Dysdera* (Araneae, Dysderidae)

THE scientific study of spiders has remained peculiarly neglected. In particular the field of systematics, until recently, has relied almost exclusively on the morphological species concept of the nineteenth century. Systematic difficulties have in turn discouraged research in other branches of spider biology. This communication summarizes an investigation into the spider genus *Dysdera* (Dysderidae), undertaken to strengthen the taxonomic foundations of a difficult but phylogenetically important group.

The life-cycles of the two British species, *Dysdera crocata* and *D. erythrina*, appear to be the same. The eggs are laid in a spherical mass, only lightly stuck together, within a thick cocoon in which the parent herself is sealed. The eggs hatch in 3-4 weeks, depending on the temperature, and about a month later the parent spider tears a hole in the cocoon through which the young escape. After seven nymphal instars, occupying approximately eighteen months, the spiderlings reach sexual maturity, and may live for another two or three years.

Although many small arthropods are acceptable as food, all the evidence suggests that woodlice form the natural diet of *Dysdera*. All woodlice appear equally acceptable, but *Armadillidium* is better able to escape predation because of its ability to roll into a ball.

Most species of *Dysdera* are characterized by an extremely restricted distribution, and the two British species are rather atypical in this respect. *D. crocata* in particular is very widely distributed, and there is no doubt that this is a synanthropic species the range of which is being con-

Table 1. RADIOACTIVITY (AS C.P.M. PER µl.) OF XYLEM SAP AND NUTRIENT SOLUTION AT TIME OF HARVEST

	2	30.8	10.6	31.8
	14	10.6	11.9	22.8

tinually increased by transportation. In direct competition it was found that *D. crocata* could displace *D. erythrina*, being larger and better able to withstand climatic extremes. However, in areas with dense populations of certain species of ant, *D. erythrina* had the advantage, although the reasons for this are not clear.

The external morphology of the two British species was examined from the point of view of practical systematics. First the changes associated with age were analysed, by examination of the successively cast exuviae of individual spiders. The growth of limb segments was considered in relation to the length of the carapace, and only very slight allometry found, except in the growth of tibia I, which in the males of both species, but particularly in *D. crocata*, increases considerably in length at the last moult, giving rise to a marked sexual dimorphism. The positions of the metatarsal trichobothria are constant at all stages of growth. Even in the adult the number and positions of leg spines is highly variable, and except in rare cases immature specimens cannot be identified by this means. The absence of strongly allometric growth having been demonstrated, comparisons between population samples of adults of the two species were made. Spines, which are generally lacking, only occur symmetrically on the fourth femur of *D. erythrina* very rarely, and therefore the presence of such femoral spines may be taken as indicative of *D. crocata* with a high degree of certainty. However, *D. crocata* not infrequently lacks femoral spines, and the absence of such spines is not indicative, therefore, of *D. erythrina*. The number of femoral spines in *D. crocata* is very variable.

The spacing of the eyes and the width of the eye group in relation to carapace width was analysed, and only characters of partial value were found. Anterior median eyes of *D. erythrina* are never less than one diameter apart, whereas in *D. crocata* they can be as little as 0.75 diameters apart. The lengths of limb segments and the proportions of the carapace in both species and sexes were examined, and the absence of characters of value in practical systematics demonstrated.

Because there is no epigyne in *Dysdera*, no use has hitherto been made of the female genitalia in systematic investigations. A comparative survey of the internal female genitalia in the Dysderidae and related families showed that these structures could be extremely valuable, not only for specific identification, but also as a guide to determining higher categories.

As a result of these and related investigations a new classification of the Dysderidae is proposed. The family is divided into four tribes: Dysderini, Harpactini, Orsolobini and Rhodini. The latter include *Rhode*, *Typhlorhode* and *Harpassa*, while the Orsolobini contain only the obscure South American genus *Orsolobus*. The Harpactini include *Dasumia*, *Harpactes*, *Holissus* and *Stalita*. The latter genus includes the species previously contained in *Minotauria*, *Stalitella* and *Parastalita*, which are no longer recognized. The remaining four genera, *Tedia*, *Stalitochara*, *Dysdera* and *Harpactocrates*, are placed in the Dysderini, but the status and position of *Harpactocrates* are dubious. The species at present included in *Harpactocrates* are a heterogeneous assemblage which may be clearly sub-divided into three groups, each probably deserving generic status. The first of these includes *H. gurdus*, *radulifer*, *ravastellus*, *drassoides*, *intermedius* and *appenicola*, and the second *H. cantabrorum*, *deminutus*, *ignavus*, *inaequipes*, *limbarae*, *romandiole*, *siculus*, *terualis* and *vernae*. In the third group, *H. egregius* and *storkani* are distinctively isolated, but it is probable that *H. marani* may also belong to this group. The position of *H. crassipalpis* remains uncertain; *H. saevus* and *rubicundus* belong to *Harpactes*.

The anatomy of the genitalia and accessory musculature was examined in detail, particularly in relation to function. The basic dysderoid plan consists of a single aperture leading off the epigastric furrow and opening into a bursa

copulatrix. There is usually a single median anterior spermatheca and frequently a posterior diverticulum. In *Dysdera* the spermatheca is bilobed and heavily sclerotized. It is associated with large glands the function of which appears to be, at least in part, to force the spermatozoa out of the spermatheca as the eggs pass through the bursa copulatrix. The posterior diverticulum is a thin walled muscular sac lined with chitinous protuberance through which drain mucus-secreting cells. During mating the male palpal organs are twisted simultaneously into the bursa copulatrix through the action of a pair of antagonistic muscles controlling the bulb and by the movements of the whole palp. The bulb bears down through a twisted sclerotized strip the contour of which helps to guide the bulb during insertion. The posterior apophysis of the bulb also helps to supplement this action, but its main function is to lock the palp into the female during the process of sperm transfer.

The emptying of the receptaculum seminis in the male palp was found to be under hormonal control, probably by a neurosecretory mechanism. It is brought about by the secretion of surrounding glands emptying through minute pores into the lumen of the reservoir. Hydrostatic pressure plays no part in the function of the male palp in *Dysdera*.

Spiders which had matured in the wild would not mate with individuals of the other species, but spiders that have been raised in isolation in the laboratory would, in some cases, mate readily with similarly treated individuals of the other species. In the latter matings the eggs were invariably found to be infertile. The presence of a genetic barrier to the formation of hybrids was further demonstrated by artificial insemination experiments, which also failed to produce fertile eggs.

Whereas mating may take place at any time of the year, eggs are only laid at certain seasons. In Britain and Northern Europe there is a peak laying season in May and June, but in North Africa *D. crocata* has two laying seasons, one in March and the other in August. The number of eggs produced by an individual fell at each laying, 60-40-20 being typical values for the first three cocoons. The proportion of fertilized eggs in each batch decreased if the spider had mated only once, but the numbers of spermatozoa in the female genitalia showed that in nature multiple matings are common.

### Tantalum and Niobium in Ascidians

It is a well known and established fact that some ascidians have a peculiar ability to accumulate vanadium from sea-water. While the vanadium content does not reach 2 p.p.m./dry weight in ordinary marine animals, it exceeds 6,500 p.p.m. in some ascidians of the order Phlebobranchia<sup>1</sup>. In other orders of ascidians and holothurians this ability is less marked or lacking<sup>2</sup>. Recently it was reported that an ascidian, *Molgula manhattensis*, contains and actively incorporates niobium<sup>3</sup>. It therefore seems probable that ascidians may also be capable of absorbing tantalum. Since no information is available about tantalum in living organisms, it is of interest to know if any tantalum is contained in ascidians beside vanadium and/or niobium.

A few hundred middle-sized mature *Styela plicata* (40-45 mm in length)<sup>4</sup> were collected at Misaki Marine Biological Station, Kanagawa, Japan, in November 1961, April 1962 and July 1962. These were thoroughly cleaned with a nylon brush, and then dried in an oven at 110°C in glass vessels, and chemically analysed. Determination of tantalum and niobium was carried out by the procedure to be described here<sup>5</sup>.

A small amount (1-2 g) of finely ground material was weighed exactly and placed in a 250-ml. beaker. Thirty-ml

concentrated hydrochloric acid and 60 ml. of distilled water were added and the beaker was covered with a watch-glass. After mild heating for 30 min on a hot-plate, the sample was filtered and washed with hot dilute hydrochloric acid. The residue was transferred into a platinum crucible, ashed and ignited. Three drops of concentrated sulphuric acid were added, and the resulting mixture evaporated and further ignited. If the material as rich in silica, the silica was removed by heating the residue with three drops of sulphuric acid and some hydrofluoric acid and evaporating to dryness. The sulphur dioxide was then expelled by heating.

The residue was fused with 2 g of sodium hydrogen phosphate, then extracted with concentrated sulphuric acid, transferred to a 100-ml. volumetric flask and, after filtering if necessary, made up to 100 ml. with concentrated sulphuric acid. An appropriate aliquot was transferred to a 50-ml. volumetric flask. A solution consisting of 1.00 ml. of 30 per cent hydrogen peroxide and 25 ml. of concentrated sulphuric acid was prepared in bulk and cooled to room temperature. Twenty-five ml. of this solution was then added to the 50-ml. volumetric flask containing the aliquot of sample solution. The flask was then stoppered and the contents thoroughly mixed. A final dilution to volume was made at room temperature. The resulting solution was compared to a reference solution prepared in an identical manner and containing an equal concentration of sulphuric acid and hydrogen peroxide. Determination of tantalum and niobium was made by measuring absorption at 285 m $\mu$  and 365 m $\mu$ , respectively.

The results are summarized in Table 1. The animals collected on November 8, 1961, were divided into two lots. The difference in content of the elements is attributed to individual fluctuations. The animals collected on April 13, 1962, were mixed and powdered into a single lot from which samples were taken for repeated analyses. The same procedure was applied to the animals collected on July 8, 1962. The results of repeated analyses for each lot coincided well within the range of experimental error. On average, *Styela plicata* was found to contain 0.023 per cent (range 0.010–0.041 per cent) tantalum and 0.025 per cent (range 0.015–0.030 per cent) niobium (all values per cent dry material). Because sufficient numbers of animals were not available we cannot say whether the fluctuations represent some seasonal or developmental variation. However, our results demonstrate the accumulation of a considerable amount of tantalum in the ascidian body. This is of interest since the presence of tantalum in living organisms has not previously been reported. The vanadium content of *S. plicata* is very low: 13 p.p.m. dry material<sup>6</sup>.

According to Carlisle and Hummerstone<sup>7</sup>, the niobium content of the sea-water was 0.01–0.02  $\mu$ g/l. for an unfiltered sample collected about 40 km south-west of Plymouth, and 0.05–0.1  $\mu$ g/l. for unfiltered and 0.005  $\mu$ g/l. for filtered water sampled at Plymouth Sound. The tantalum content of the sea-water around the Pacific coast of Japan was reported by Hamaguchi *et al.*<sup>8</sup> to be  $\leq$  0.02  $\mu$ g/l. Although no other data are available concerning the tantalum and niobium content of sea-water, it is certain that both elements exist in sea-water at extremely low concentrations.

The presence of niobium in ascidians was reported earlier in *Molgula manhattensis* by Carlisle<sup>3</sup>, who also investigated the relationship between vanadium and niobium. He found niobium (25–75 p.p.m.) only in individuals with vanadium content less than 2 p.p.m.,

and not in those which contained as much vanadium as 29–98 p.p.m.

Hamaguchi *et al.*<sup>8</sup> were able to show by the quantitative neutron activation analysis method that the average tantalum content of the sea bottom clays is: 0.9 g/ton for Pacific red clay, 1.2 g/ton for Japan Sea red clay, 0.2 g/ton for Pacific foraminiferan ooze, and 0.2 g/ton for Pacific volcanic ooze. No specific accumulation of tantalum in the sea bottom clays was observed except in some red clays.

It is therefore likely that the tantalum contained in these ascidian results from active absorption by the animals. The site and the mechanism of the selective absorption of vanadium by ascidians have recently been the subject of active discussions<sup>9</sup>. It has also been shown that vanadium exists as a proteinium salt of disulphato-vanadium(III) acid<sup>10</sup> in blood cells, presumably in their vanadophores<sup>11</sup>. However, despite some attractive interpretations, we are almost completely ignorant of the part played by vanadium in the biology of ascidians. At least it seems that vanadium may be replaceable by niobium<sup>3</sup> or by iron<sup>12,13</sup>. Our results, showing the presence of tantalum and niobium in an ascidian in a quantity exceeding that of vanadium, open up a new aspect of this problem.

We thank Mr. K. Matsuda, of the Institute of Physical and Chemical Research, and the staff of the Misaki Marine Biological Station, for their help.

## Toxicity of Rubber Stoppers to *Daphnia magna* Straus

In 1957, DeWitt<sup>1</sup> directed attention to the mortality of aquatic insects and fishes caused by latex tubing in experimental apparatus. While examining the effects of reduced oxygen concentrations on zooplankton, we found that water in direct contact with laboratory-grade rubber stoppers was acutely toxic to *Daphnia magna*.

The apparatus included a series of cylindrical glass chambers. Water was delivered and removed through glass tubes mounted in black rubber stoppers. All other connexions were made of vinyl tubing. In several preliminary experiments with first instar *D. magna*, the mortality of control animals was unusually high. Results were the same in experiments carried out to evaluate the effect of static and flowing-water conditions on heavy metal toxicity. Subsequently, we covered the black rubber stoppers with vinyl food wrap ('Saran'), and mortality among control animals was eliminated.

Bioassay of the stoppers was then undertaken. First instar *D. magna* from mixed broods were used in the assay. New rubber stoppers were sliced and placed in

culture dishes, each containing 10 animals. Except for rubber stopper slices, conditions were identical for control animals. The animals were not fed during the exposure. All experiments were carried out at 20° C.

In three separate tests, a total of 110 animals were exposed to water containing rubber slices; all were dead at the end of 24 h. In most cases, the animals were moribund in less than 8 h.

Grey neoprene stoppers were also assayed and found to be toxic. Survival time was slightly longer, but all the exposed animals were dead after 48 h. There was no mortality among control animals.

There appeared to be little value in quantifying the results further, and we have continued our experiments in apparatus equipped with ground-glass tapered joints.

## FORESTRY

### Heterophyllous Shoots in *Betula papyrifera*

LEAVES of two morphological types occur on long shoots of tree crowns in many species of *Betula*. Those at the shoot base frequently differ from leaves closer to the shoot tip in venation, size, toothiness and other characteristics. The first group of leaves (early leaves) appears at or shortly after bud opening, and the second (late leaves) later in the growing season after the first leaves are well expanded. Early leaves are also found on short shoots, that is, shoots the internodes of which fail to elongate more than a few mm. Late leaves are lacking on short shoots. In a report on leaf dimorphism in *Populus trichocarpa*, Critchfield<sup>1</sup> stated that differences in leaf form were due to differences in ontogeny between early and late leaves. Early leaves formed in the growing season preceding their expansion. Their development was arrested and they over-wintered as embryonic leaves, continuing development the following spring. Late leaves over-wintered as leaf primordia or were not initiated until the growing season in which they expanded. Consequently their formation was not interrupted in the embryonic stage and their form differed from that of early leaves. These investigations have now been extended to an evaluation of bud contents, shoot growth, and heterophylly in *Betula papyrifera* Marsh. growing in north central Wisconsin (U.S.A.).

Buds located on twig tips and expected to produce long shoots were collected late in April, before bud opening, and again in late September during leaf fall. Buds located on lateral short shoots and expected to produce short shoots were collected in April only. Embryonic leaves and leaf primordia within these buds were counted and their lengths measured with a mm rule or ocular micrometer.

Before bud opening five branches on each of five trees were selected for shoot measurement. Internode and leaf elongation measurements were made at frequent intervals on the terminal long shoot of each branch and on the most distal short shoot of the two-year-old portion. Leaves were measured from tip to point of attachment to stipules. Internodes were numbered according to the leaf which terminated them.

The first pair of leaves on the long shoots began to unfold about May 15. They grew rapidly for two weeks, then slowed and ceased growing in the third week. The third leaf appeared when the first two were more than half grown, around May 30 on most branches. Succeeding leaves appeared at intervals of approximately five days until a mean total of 5.8 leaves per shoot had emerged. Because of the interval between the occurrence of the first

two leaves and succeeding ones, and their general firmer texture and more apparent double toothiness, leaves 1 and 2 were classified as early leaves and the remainder as late leaves.

Late leaves elongated at a rate similar to that of early leaves and their growth was usually complete in 2-3 weeks. Growth in all but one or two leaves ceased after July 29. Final mean length of early leaves, calculated from those which completed growth without serious injury, was 8.9 cm. Final mean length of late leaves was not calculated since injury due to disease and insect arrested many before growth ceased. There was a tendency for each late leaf to have a shorter final length than that formed previously on the same shoot.

Internodes 1 and 2 of long shoots seldom exceeded 1 mm in final length. The period of rapid elongation of an later internode lay within that of the leaf which terminated it, but was completed a few days sooner. Elongation of the final internode was usually complete by the time the first late leaf had ceased growing. There was a tendency for final length to decrease in succeeding internodes after internode 3. Mean final length of internodes on was 21.4 mm. Mean total shoot length was 85.5 mm only 6.3 per cent of which was made of internodes 1 and 2.

Most of the short shoot buds produced 2 leaves; a few produced 3 or 4. All these leaves resembled the early leaves formed on long shoots. Mean number of leaves produced by short shoots was 2.4. Final mean length of lateral shoot leaves was 10.2 cm, slightly longer than early leaves on long shoots. Internodes did not exceed 1 mm on lateral shoots.

Both embryonic leaves and leaf primordia were found in the spring within each bud expected to produce a long shoot. The former were clearly leaf-like, with well defined teeth, petiole and veins. The latter were small lobed structures not yet exhibiting detail. The embryonic leaves fell into two size classes with a break of 2-6 mm separating them. Large leaves had a mean length of 6.4 mm and small leaves a mean length of 1.2 mm. The large leaves were pubescent and firm in texture. Some of the largest of the small leaves were pubescent, but the majority were glabrous, translucent and delicate in texture. The leaf primordia ranged in length from 0.2 to 0.3 mm. The mean number of large leaves per long shoot bud was 2.1 and the mean number of small leaves was 2.6. Mean number of primordia was 1.1. Spring short shoot buds contained the same type of leaves but had on the average slightly more large leaves (2.7) fewer small leaves (0.9), and about the same number of primordia (1.0). Mean lengths in each class were approximately the same as in the long shoot buds. Autumn long shoot buds contained an average of 2.0 large leaves, 1.2 small leaves and 1.6 primordia. Mean lengths of these were 5.2, 1.3 and 0.5 mm, respectively (Table 1).

Table 1. NUMBERS OF EARLY AND LATE LEAVES ON SHOOTS AND CONTENTS OF SPRING AND AUTUMN BUDS OF *Betula papyrifera*

No. per shoot		Spring buds		No. per bud		Autumn buds	
Summer shoot		Embryonic Primordia		Embryonic Primordia		Embryonic Primordia	
leaves		leaves		leaves		leaves	
Early	Late	Large	Small	Large	Small	Large	Small
2.0	3.8	2.1	2.6	1.1	1.2	2.0	1.6

A comparison of bud contents with summer leaf production showed that approximately 2 large, firm-textured embryonic leaves were found in both spring and autumn buds. Their position and number corresponded to that of the early leaves expanded during the growing season. The number of late leaves produced during the summer was higher than the number of small embryonic leaves found per spring bud. Hence, late leaves developed not only from small embryonic leaves, but also from primordia present in the spring bud. Apparently early leaves over-wintered as large embryonic leaves while late leaves over-wintered either as small embryonic leaves or as primordia. Before bud break in the spring the over-

entering primordia were stimulated to continue development into embryonic leaves and were replaced by newly forming primordia. Potential late leaves were present in short shoot buds but were suppressed.

## ENTOMOLOGY

### Structure-activity Relationships among Insecticidal Compounds derived from Chlordene

RECENT investigations<sup>1-3</sup> demonstrated the value of metabolic inhibitors such as pyrethrin synergists as tools in the investigation of structure-activity relationships among the 'cyclodienes' type insecticides. Thus, the wide variations in toxicity to the housefly found in several groups of related cyclodienes were found to be reduced in the presence of the pyrethrin synergist 'Sesamex', a phenomenon accompanied, in the case of compounds examined *in vivo*, by inhibition of metabolic conversions<sup>1,3</sup>.

The use of 'Sesamex' is further illustrated in recent investigations of chlordene (1; Fig. 1) and related compounds. Heptachlor (2), which is known to be converted to a persistent epoxide, m.p. 160°, in mammals<sup>4</sup> and the housefly<sup>5</sup>, is considerably more toxic than chlordene (1) to the housefly. Stereochemical investigations of Riemshneider<sup>6</sup>, chemical investigations of Davidow and Adamski<sup>4</sup> and inspection of molecular models suggest structure (3) for this epoxide, while the mode of formation of a second epoxide, obtained indirectly from heptachlor<sup>7</sup>, indicates that it has the structure (4). Chlordene (1) reacts with peracids to give the epoxide (5) (ref. 8) and is converted by the housefly into an epoxide-like compound<sup>9</sup> now identified as compound (5) (infra-red spectrum). Gas-liquid chromatographic analysis, on an Apiezon L-treated 'Celite' column, of acetone tissue extracts of live houseflies treated with chlordene (peak I) revealed the presence of at least two other compounds (peaks III and IV in order of retention time) in addition to the epoxide (peak II). No substances other than chlordene were found in heat-killed insects similarly treated. Compounds corresponding to peaks III and IV were isolated from insect extracts by thin-layer chromatography on alkaline alumina and compound (III) was identified (infra-red spectrum) as a 1-hydroxychlordene (6), also prepared from the 1-bromo-compound (7) by alkaline hydrolysis. Examination of acetone extracts of houseflies treated with compound (5) or (6) revealed the presence, in the case of a substance which co-chromatographed on thin-layer chromatography and gas-liquid chromatography with compound IV and suggested that this might be a hydroxy-epoxide such as compound (8), arising by oxidation of (6), hydroxylation of (5), or simultaneous hydroxylation and epoxidation of chlordene. Perbenzoic acid oxidation of compound (6) then gave a hydroxy-epoxide (8) having an infra-red spectrum identical with that of compound IV isolated from chlordene treated houseflies. Although epoxide (5) might be hydroxylated at one or more of several positions, the fact that compound IV could not be resolved and the clarity of its infra-red spectrum suggested that it was mainly compound (8); if free isomeric mono-hydroxy compounds are formed the amounts present must be small. Compounds (5) and (8) were non-toxic when injected into houseflies. Acetone extracts of houseflies treated with epoxide (5) so contained compounds which may be chlordene-diols

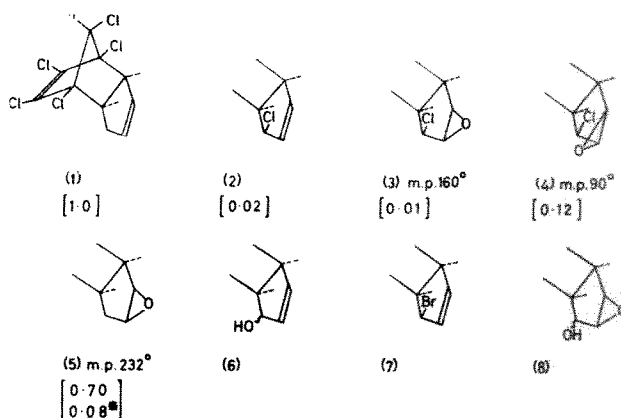

Fig. 1. Chlordene and partial structures of compounds derived therefrom by modification of the unchlorinated ring. Figures in square brackets are corresponding  $LD_{50}$ 's in  $\mu\text{g}$  per female housefly (ref. 2). \*  $LD_{50}$  following pretreatment with 'Sesamex'.

since their chromatographic behaviour was similar to that of synthetic chlordene glycols. The latter were clearly distinguished from the other compounds discussed since they remained near the point of application in most of the thin-layer systems used.

Although chlordene was recovered unchanged from heat-killed flies, rinses of the vessels which contained them showed traces of more polar compounds, and experience with similar compounds<sup>3</sup> suggested that chlordene might undergo atmospheric oxidation. This was verified by the decomposition which resulted from several hours exposure of chlordene to air and light on glass plates. Further, chlordene exposed to ultra-violet light for a few minutes gave a complex mixture of products from which compounds (5) and (6) were isolated. These results indicate the susceptibility of the chlordene molecule to oxidative conversions.

Since chlordene is converted *in vivo* into the epoxide readily obtained chemically, the structure-activity relationships in this group of compounds may be considered in detail. The apparent toxicities to the housefly of compounds (3), (4) and (5) decrease in this order (Fig. 1), the last-mentioned compound being only slightly more toxic than its precursor (1) (ref. 2). Since the *in vivo* epoxidation of heptachlor appears to be a toxication process<sup>5</sup>, it seemed that the relatively low toxicity of chlordene might result from its inability to form a stable epoxide in the housefly<sup>9</sup>. Penetration investigations with chlordene have confirmed that its rapid disappearance from housefly tissue is accompanied by a temporary accumulation of the epoxide, the levels of both compounds falling to zero within, for example, 8 h following application of 0.4  $\mu\text{g}$  chlordene per female fly. Fig. 2 shows the effect of a prior application of 'Sesamex' on the fate of chlordene epoxide (5), topically applied to the housefly. The discovery of ring hydroxylation as a detoxication route for chlordene epoxide helps to explain the stabilizing effect of 'Sesamex', an inhibitor of biological oxidations, on this epoxide *in vivo*, since the more obvious route involving hydrolytic cleavage of the epoxide ring rather than oxidation. The stabilization of compound (5) *in vivo* is accompanied by an approximately ten-fold increase in its toxicity (Fig. 1), indicating a potentially higher toxicity than that observed in normal toxicity tests. In contrast, epoxides (3) and (4) are found to accumulate in the housefly at about the same rate following their topical application and both appear to be as persistent as diel-drin<sup>10</sup>. This finding accords with the lack of any pronounced synergistic effect with 'Sesamex' and indicates that the observed toxicities of these compounds approach their intrinsic toxicities (that is, toxicities in the absence of detoxication). The intrinsic toxicity of chlordene epoxide

Fig. 2. Effect of pretreatment with 'Sesamex' (5 µg/fly) on the recovery, determined by gas-liquid chromatography<sup>1</sup>, of chlordane epoxide from the housefly. Dotted curves, cuticle rinses; full lines, tissue extracts. Insecticide only, ●; insecticide plus 'Sesamex', ▲. Dose, 0.37 µg/fly

appears to lie between those of the two heptachlor epoxides and may be greater than the maximum so far observed since the recoveries from insect tissue were incomplete, even in the presence of 'Sesamex'. The results suggest that the different toxicities of the heptachlor epoxides (3) and (4) may be a true consequence of their stereochemical difference, while the apparent low toxicity of chlordane epoxide results from an increased liability to detoxication arising from the absence of the additional chlorine atom present in (3) and (4). Rather than possessing a more positive role in toxicity, therefore, this chlorine atom may serve simply to shield a vulnerable position of the chlordane molecule from direct hydroxylation while also screening the epoxide rings from enzymatic attack. A toxicological investigation of the chlordane epoxide having its oxygen ring in the same configuration as that of compound (4) would be of interest in relation to this hypothesis.

## MICROBIOLOGY

### Nomenclature of Living Parasite Material

THE term 'strain', with its connotation of ancestry, descent, race or stock<sup>1</sup>, is clearly appropriate for living material which is kept available for experimental purposes by being serially passaged in laboratory animals or in culture. Material maintained in this way, being continuously reproducing, is subject to selection. It may, therefore, alter in its biological characteristics in the process of passage and so be unsuitable for reference purposes for long-term experimentation and unrepresentative of the populations existing in Nature and from which it was derived.

It is to Weinman and McAllister<sup>2</sup> that the credit is due for directing attention to the fundamental significance of

the viable storage of parasitic organisms at low temperatures in affording material in which reproduction is arrested and biological characters are stabilized. A separate term is now required to convey this implication of the stabilization of biological characters in preserved material and to distinguish preserved from 'strain' material. The word 'stabilate' is now proposed for this purpose. A 'stabilate' may be defined as a population of an organism preserved in viable condition on a unique occasion. There will be only as many examples of a stabilate as there were individual samples of it laid down on the unique occasion. It will therefore be possible to designate each stabilate by a unique code letter or number.

We thank Prof. A. McIntosh, of the Department of English Language in the University of Edinburgh, for advice regarding the choice of a suitable word.

### Distribution of Respiratory Quinones in 2,5-di-tert-amyl-p-benzoquinone-sensitive and -resistant Bacteria

A NUMBER of *p*-benzoquinones have been shown to inhibit bacterial growth<sup>1-3</sup> and the succinic oxidase activity of beef heart<sup>4,5</sup>. In view of the role of quinones in the electron transport and coupled phosphorylation of bacteria<sup>6-8</sup> it seemed of some interest to determine the relationship between susceptibility to *p*-benzoquinones and the distribution of respiratory benzoquinones and naphthoquinones in bacteria.

The susceptibility to 2,5-di-tert-amyl-*p*-benzoquinone (DAQ) of a number of strains of bacteria, the content of ubiquinone and vitamin K of which was known, was discovered by plating suitable dilutions of broth cultures on trypticase soy agar (Baltimore Biological Laboratory Inc.) containing a range of concentrations of DAQ and incubating at 37° for 18-36 h. The lowest inhibitory concentration was taken as that which reduced the count of readily visible colonies to less than 1 per cent compared with control plates containing no DAQ; with some bacteria colony formation was completely inhibited, while with others minute colonies could be detected on careful examination. Although it was not possible to obtain a precise estimate of the colony count with *Proteus vulgaris* due to spreading of the individual colonies, since they appeared to be no reduction in either the number of 'foci' or the overall amount of growth when plated on medium containing 300 µg/ml. of DAQ, the organism was recorded as being resistant to this concentration of DAQ. Table 1 shows that, of the small range of bacteria tested, those which contain vitamin K alone were sensitive to 30 µg/ml or less of DAQ, while those bacteria which contain (1) ubiquinone either alone or in combination with vitamin K, or (2) neither of the two respiratory quinones were resistant to at least 300 µg/ml. (the maximum concentration of DAQ which it is practicable to include in the medium).

We have previously reported that the antibacterial activity of DAQ appeared to be virtually restricted to strains of *Staphylococcus aureus*<sup>9</sup>. This was probably a reflexion of the screening method used and also the marked sensitivity of *Staph. aureus* to DAQ later demonstrated<sup>3</sup>. Although we have not investigated the respiratory quinones of *Staph. aureus*, in view of its sensitivity to DAQ it would probably contain only vitamin K; Bishop Pandya and King<sup>10</sup> have shown that *Staph. albus* contains vitamin K, but no ubiquinone.

Table 1. SUSCEPTIBILITY TO 2,5-DI-*tert*-AMYL-*p*-BENZOQUINONE AND PRESENCE OF RESPIRATORY QUINONES IN BACTERIA

Organism	Respiratory quinones*		Inhibitory conc. of 2,5-di- <i>tert</i> -amyl- <i>p</i> -benzoquinone ( $\mu$ g/ml.)
	Ubiquinone	Vitamin K	
<i>Micrococcus lysodeikticus</i> N.C.T.C. 2665	—	+	30
<i>Corynebacterium diphtheriae</i> P.W.8	—	+	10
<i>Bacillus megaterium</i> N.C.T.C. 9848	—	+	3
<i>Bacillus subtilis</i>	—	+	10
<i>Serratia lutea</i>	—	—	10
<i>Lactobacillus casei</i>	—	—	> 300
<i>Aerobacter aerogenes</i> N.C.T.C. 418	+	—	> 300
<i>Pasteurella pseudotuberculosis</i> N.C.T.C. 1101	+	—	> 300
<i>Chromobacter prodigiosum</i> N.C.T.C. 1877	+	—	> 300
<i>Achromobacter hartlebii</i> N.C.I.B. 8129	+	—	> 300
<i>Pseudomonas aeruginosa</i>	+	+	> 300
<i>Proteus vulgaris</i>	+	+	> 300
<i>Escherichia coli</i>	+	+	> 300
<i>Escherichia coli</i> K12	+	+	> 300
<i>Escherichia coli</i> B	+	+	> 300

\* Data on types of quinones present in organism 1 were taken from ref. 12, organisms 2–13 from ref. 10, and for organisms 14 and 15 from ref. 13. + Present; — not detected.

The sensitivity to DAQ of bacteria in which vitamin K is the only quinone involved in electron transport, and the relative resistance of bacteria which either possess the alternative pathway through ubiquinone or do not contain quinone-mediated electron-transport system, suggest that DAQ probably interferes with the function of vitamin K but not with that of ubiquinone. In view of the as yet incomplete knowledge of the systems of electron transport and coupled phosphorylation in bacterial cells, selective inhibition by a *p*-benzoquinone of bacteria in which electron transport is vitamin K-dependent could be of value in the further elucidation of these systems<sup>11</sup>.

We wish to thank Dr. H. K. King for providing us with number of the bacterial cultures and Dr. D. C. Edwards for a culture of *Corynebacterium diphtheriae* P.W.8. This work was supported by a grant from the Cancer Council of Western Australia.

## VIROLOGY

### Activity of 6-Aminonicotinamide against *Vaccinia* Virus *in vitro*

6-AMINONICOTINAMIDE (6-AN), a potent nicotinamide antagonist<sup>1,2</sup>, was tested for its activity against vaccinia virus, viral cytopathic effects not having been demonstrated in vaccinia-infected tissue cultures in the presence of small amounts of the compound.

All experiments were performed in tube cultures of chick embryo fibroblasts (CEF), propagated in Hanks's balanced salt solution containing 0.5 per cent 'lactalbumin' hydrolysate, 0.1 per cent 'Yeastolate' and 2 per cent newborn calf serum at pH 7.2. For maintenance of cultures, Earle's balanced salt solution was substituted

and the pH increased to 7.6. Cytopathic end points were expressed as the lowest dilution which infected 50 per cent of cultures ( $TCD_{50}$ ) calculated by the method of Reed and Muench<sup>3</sup>.

Vaccinia virus, previously re-passaged in CEF, was stored in individual vials at  $-65^{\circ}\text{C}$  and titrated to determine the plaque-forming units per millilitre (P.F.U./ml.). For use in infectivity tests a multiplicity of 5 P.F.U./cell contained in 0.3 ml. was used.

In a typical experiment, 6-AN of a concentration of 10  $\mu$ g/ml. was added 3 and 6 h before, and immediately after, virus adsorption. A control series containing no 6-AN was also included.

Immediately before infection with virus, all media were removed from the tubes and stored. Adsorption of virus to the cells was allowed for 1.5 h, the tubes were drained and residual virus removed. The monolayers were then washed twice with 1.5 ml. of medium and the original media were replaced. After incubation at  $36^{\circ}\text{C}$ , random samples were removed from each group at 24-h intervals, the cytopathic effect (CPE) was assessed visually, the tubes frozen and thawed to liberate intracellular virus, and the individual group samples pooled. At least four tubes were removed for each pool.

It was noted that CPE progressed in the usual manner in tubes without 6-AN, with complete degeneration between the second and third day. In tubes containing 6-AN, however, no CPE was evident except in tubes challenged with 6-AN after virus adsorption when discrete focal areas of viral destruction were seen. It was also seen that the usual change in pH was not so marked in tubes containing 6-AN. All pooled samples were titrated simultaneously on CEF monolayers and the  $TCD_{50}$  was determined.

Fig. 1 demonstrates that the longer 6-AN was in contact with the cells before virus infection, the more inhibitory was its action, although a significant decrease in viral yield was obtained when 6-AN was added to the cultures immediately after virus adsorption. Progeny was diminished approximately 1,000-fold when 6-AN was added 6 h before virus and 100-fold when it was added after virus.

Reversal of the action of 6-AN was obtained by the addition of 100  $\mu$ g/tube of nicotinamide. When added at the same time as 6-AN, complete reversal was obtained, but when added after virus adsorption the increase in virus yield was related to time of addition and was never complete. Similarly, removal of medium containing 6-AN and replacing with fresh medium without 6-AN produced a higher yield of virus, but never as high as that of untreated cultures or of nicotinamide-treated cultures.

Fig. 1. ■, No 6-AN; □, 6-AN added immediately after virus adsorption; ○, 6-AN added 3 h before virus infection; ●, 6-AN added 6 h before virus infection.

Tests for direct neutralizing and toxic effects of 6-AN on vaccinia virus proved negative; this implies that its action is directed against intracellular synthesis of virus.

### Haematological Changes in Viral (MHV-3) Murine Hepatitis

In earlier work we investigated some biochemical<sup>1</sup> and biological<sup>2</sup> aspects of hepatitis induced in mice by mouse hepatitis virus strain 3 (MHV-3).

In the present communication, in order to investigate extrahepatic pathology due to MHV-3 (ref. 3), the peripheral blood as well as the lymphopoietic and haemopoietic systems were examined during various stages of the disease. Moreover, the virus concentration in the peripheral blood, bone marrow, spleen and lymph nodes was determined.

Eighty mice of the NMRI-strain, weighing about 12 g and fed on the 'Altromin' diet, were divided into four groups of 20 animals each, indicated as A, B, C and D. Mice of groups A, B and C were inoculated intraperitoneally with 100 LD<sub>50</sub> of MHV-3 virus; mice of group D served as controls.

The number of red cells, white cells, platelets and reticulocytes in the peripheral blood was determined for eight animals from each group, picked at random among the survivors at 24 h (group A), 48 h (group B) and 72 h (group C). Also determined were the haemoglobin concentration and differential white cell count.

Five animals from each group were then killed by decapitation; the bone marrow was taken from the femoral diaphysis of each mouse; smears were prepared and the myelogram determined. Furthermore, from the animals killed 72 h after virus inoculation (group C), samples of blood, bone marrow, lymph nodes and spleen were obtained and assayed for viral content (the LD<sub>50</sub> was determined according to the method of Reed and Muench<sup>4</sup>). From the spleen and lymph nodes of these animals histological preparations were also made.

The results summarized in Table 1 show a statistically significant drop in haemoglobin, white cells, reticulocytes and platelets. The diminution progresses with time being particularly conspicuous in the terminal stage of the disease (72 h), when marked anisocytosis and poikilocytosis of erythrocytes also occur. The differential count starting at 48 h, shows a marked absolute diminution of lymphocytes and, to a lesser degree, of monocytes and eosinophilic polymorphonuclear leucocytes. These alterations, which become more evident as the disease progresses, are statistically significant. 72 h following virus inoculation, absolute neutropenia is detectable. Examination of smears reveals that granulocytes are mainly represented by juvenile elements with little segmentation of the nuclei.

Table 2 shows a diminution in the elements of the erythropoietic series as compared with the leucopoietic series. The leucopoietic series shows a marked relative increase of the more immature elements (myeloblasts and promyelocytes) compared with the more mature ones (metamyelocytes and granulocytes). Furthermore, relative increase of haemocyctoblasts is present.

A histological examination of axillary lymph node showed a marked diffuse hyperplasia of the reticuloendothelium, with subsequent obliteration of sinuses of the medulla and dissociation of follicles of the cortex. The follicles displayed a high degree of hyperplasia, being sometimes reduced to a small clump of lymphoid element at the periphery of the lymph node. The lymphoid cell showed frequent karyorrhexis and karyolysis. Marked hyperplasia of the reticuloendothelium of peripheral sinuses also occurred. The endothelium of sinuses of the medulla was hypertrophic and hyperplastic, with packing of the endothelial cells which often resemble multinucleated giant cells. Mitoses were often seen in reticular cells. Similar changes were detected in mesenteric lymph nodes.

The histological examination of the spleen showed a high degree of congestion of oedema. In the cortex there was a marked decrease in follicle volume. The follicle remains were made up mainly of cells of the lymphoblastic and histiocyte type, often nucleolated and in mitosis. Therefore, there were few mature lymphoid elements concentrated in a narrow band at the periphery of the follicles or scattered throughout the parenchyma. In the germinal centres there were frequent cellular changes with fragmentation of the nuclear membrane and chromatolysis. Scattered areas of necrosis were also evident.

The results summarized in Table 3 show that the virus is present in high concentration in the spleen and bone marrow, less in the peripheral blood and lymph nodes.

Table 1. VALUES OF HAEMOGLOBIN, RED BLOOD CELLS, LEUCOCYTES AND PLATELETS IN NORMAL MICE AND IN MICE INFECTED WITH 100 LD<sub>50</sub> OF MHV-3 VIRUS, AT DIFFERENT TIMES FOLLOWING INOCULATION

\* From eight determinations, each on a different animal.

For cell counts and haemoglobin determination the tail venous blood was used. Differential white cell counts were made on 500 elements.

Table 2. BONE MARROW PICTURE IN NORMAL MICE AND IN MICE INFECTED WITH 100 LD<sub>50</sub> OF MHV-3 VIRUS AND KILLED AT 72 H

Per cent	Normal mice Mean values* ± S.D.	Infected mice Mean values* ± S.D.	P
Haemocytoblasts	1.36 ± 0.59	3.38 ± 0.81	< 0.01
Proerythroblasts	1.44 ± 0.26	1.14 ± 0.63	> 0.05
Basophilic erythroblasts	13.22 ± 1.60	5.16 ± 0.64	< 0.001
Polychromatic erythroblasts	3.83 ± 0.81	2.56 ± 0.69	> 0.05
Orthochromatic erythroblasts	5.12 ± 1.09	3.38 ± 0.67	< 0.05
Myeloblasts	5.78 ± 1.00	25.40 ± 2.06	< 0.001
Promyelocytes	5.69 ± 0.84	15.30 ± 1.69	< 0.001
Myelocytes	15.54 ± 1.46	16.22 ± 1.49	> 0.05
Metamyelocytes	21.30 ± 1.64	13.24 ± 1.96	< 0.001
Granulocytes	23.46 ± 1.45	12.46 ± 1.98	< 0.001
Megakaryocytes	0.40 ± 0.46	0.34 ± 0.11	> 0.05
Lymphocytes	1.32 ± 0.44	0.74 ± 0.33	< 0.05
Monocytes	0.68 ± 0.28	0.40 ± 0.22	> 0.05
Plasmacytes	0.39 ± 0.19	0.24 ± 0.11	> 0.05

\* From five determinations each on a different animal. In each smear 1,000 cells were counted (May-Grünwald-Giemsa staining).

The peroxidase reaction was used to differentiate haemocytoblasts from myeloblasts. Only the 72-h values are reported in the table, as they were the most significant.

Table 3. VIRUS CONCENTRATION IN PERIPHERAL BLOOD, BONE MARROW, SPLEEN AND AXILLARY LYMPH NODES OF MICE INFECTED WITH 100 LD<sub>50</sub> OF MHV-3 VIRUS 72 H PREVIOUSLY

Materials	LD <sub>50</sub>
Blood	10 <sup>-5.25</sup>
Bone marrow	10 <sup>-4.16</sup>
Spleen	10 <sup>-6.10</sup>
Axillary lymph nodes	10 <sup>-4.15</sup>

From the results presented here, the following conclusions can be drawn: (1) The hypoplasia of the erythroid series detected in the bone marrow, and particularly the considerable pathological changes of these elements, might be responsible for the marked and progressive anaemia, reticulocytopenia and diminution of haemoglobin noted in the peripheral blood. (2) The marked maturative delay and pathological changes observed in the myelopoietic series of bone marrow and the histological damage present in cells of the lymphopoietic regions of the organism (spleen and lymph nodes) might account for the leucopenia. (3) The alteration of the maturative process of megakaryocytes in the bone marrow might explain the marked thrombopenia of the peripheral blood.

The high virus concentration in the bone marrow and lymphopoietic tissues suggests that the aforementioned changes might be produced by an active multiplication of the virus in these organs.

## GENETICS

### Inheritance of Self-incompatibility and Brown Keel Tip in *Lotus corniculatus* L.

*Lotus corniculatus* is a segmental allotetraploid<sup>1,2</sup> which frequently exhibits chromosomal tetrasomic inheritance<sup>3-7</sup>. We have investigated the inheritance of pubescence, a chlorophyll deficiency, cyanogenesis, flower colour, streaks on the corolla, keel tip colour and self-incompatibility. We obtained evidence for chromosomal tetrasomic inheritance with each characteristic studied. However, we also found a number of crosses which do not give good fits to those expected with tetrasomic inheritance and feel these warrant further study.

Our most extensive investigation is of self-incompatibility, a continuation of work described previously<sup>8</sup>. We developed a technique, based on that of Picard and

Demarly<sup>9</sup>, that permits us to distinguish between compatible and incompatible matings. This technique involves growing pollen on an agar medium which is pretreated with stylar extracts. Two plant families were studied. One consisted of 19 S<sub>1</sub> progeny and their relatively self-fertile parent. These were tested in all possible combinations. The other consisted of cross-progeny of two unrelated plants. Two cross-progenies of eight plants each (the one reciprocal to the other) were tested in all possible combinations. The self-progeny group of plants gave a reasonably good fit to the pattern expected if self-incompatibility is determined by S-alleles inherited tetrasomically at a single locus. The two cross-progenies gave reasonably good fits to the pattern expected if self-incompatibility is determined by S-alleles inherited disomically at two loci. If we allow for the two different segregation patterns in the two families, our data accord with the hypothesis that we are dealing with a *Nicotiana*-type gametophytic oppositional incompatibility system. We have to allow for compatibility due to dominance in the pollen grain. When a recessive S-allele present in the pollen is matched in the style but a dominant allele in the same pollen grain is not matched, the pollen is compatible.

These studies suggest the following hypothesis on which further studies may be based. The four chromosomes carrying the S-alleles are homologous in the self-progeny, so we get random pairing by twos to give chromosomal tetrasomic inheritance. The four chromosomes carrying the S-alleles in the cross-progeny consist of two structurally differentiated pairs to give disomic segregations at two loci. If this is true, we should be able to find plants which will produce progeny that segregate tetrasomically in some crosses and disomically in others, and there should be intermediate segregations.

This hypothesis should also be tested with other segregating characters. A procedure that may be used is to cross a quadruplex with a nulliplex plant and examine segregations after back-crossing to the nulliplex. If there is a tendency for the two chromosomes from one parent to pair together (that is, two carrying the dominant allele), there should be an increase in simplex progeny compared to the 1 duplex : 4 simplex : 1 nulliplex expected with random chromosomal tetrasomic inheritance. Conversely, a tendency for one chromosome from one parent to pair with one from the other should result in a decrease in simplex progeny. The progeny genotypes may range from all simplex to 1 duplex : 2 simplex : 1 nulliplex, and expected phenotypic ratios for complete dominance may range from all the dominant phenotype to 3 dominant : 1 recessive. These extremes correspond to ratios expected with disomic inheritance at two loci. If we get the extreme condition and one pair of chromosomes is homozygous and the other heterozygous at this locus, we would expect simple disomic segregation ratios. However, a small degree of tetrasomic pairing would be expected to break down disomic patterns. If this hypothesis were valid, we would expect duplex siblings to differ from each other when back-crossed to the same recessive parent. Also, we must allow for the possibility that the degree of preferential pairing may be influenced by environmental effects so that test-crosses made at different times may segregate differently. On the other hand, test-crosses made to different nulliplex plants at one time should not differ significantly.

It is obviously very difficult to test an hypothesis as flexible as this. It is possible to reconcile most of the data we have obtained so far with this hypothesis. Other published data, such as that of Buzzell and Wilsie<sup>6</sup>, also appear to fit this hypothesis. It accounts for the excess of brown keel tip they obtained when they backcrossed duplex with nulliplex plants. It does not account for the deficiency of brown keel tip they observed with simplex crosses. However, we have evidence that supports their postulate that another locus is segregating restraint<sup>10</sup> or

suppressor genes that reduce the proportion of brown keel tip plants. Our evidence is that at least one locus that is involved in the expression of cyanogenesis is also involved in the expression of keel tip colour. Plants recessive for the allele at the suppressor locus are both acyanogenetic and yellow keel tip. This suggests that the duplex  $\times$  nulliplex segregations they present underestimate the proportion of plants duplex and simplex at the brown keel tip locus. An increase in this ratio is in agreement with the hypothesis for preferential pairing presented here, and disagrees with the postulate that ratios of less than 5:1 are a result of equational chromatid segregation. The observed low frequency of quadrivalents per cell<sup>3</sup> is also evidence against equational chromatid segregations.

We thank the National Research Council of Canada for support.

### Taste Sensitivity to Phenyl-thio-carbamide and Endemic Goitre among Pewenche Indians

THE tasting thresholds to phenyl-thio-carbamide (PTC) and the clinical characteristics of the thyroid gland were determined in 88 women and 70 men belonging to the Pewenche branch of the Araucanian Indians. Most of the subjects were born (and all of them lived) in the geographically isolated Pedregoso Valley in the Chilean Andes, 38° 32' S. The total population of the valley is of about 1,000 persons.

According to Nagel *et al.*<sup>1</sup>, who examined blood groups and haptoglobin types, this community represents a genetic isolate, and exhibits a high incidence of endemic goitre. Preliminary knowledge of the fertility trends of the subjects and of their pedigree relationships makes it possible to estimate the mean inbreeding coefficient,  $\alpha$ , as 0.0105. The mean age of the Indians studied was 35.4 years with a standard deviation of 16.38, ranging from 7 to more than 70 years.

Table 1 shows the percentage distribution of the types of thyroid gland morphology, either normal or goitrous; the last category has been subdivided into diffuse and nodular varieties. Table 2 summarizes the distributions of the observed tasting thresholds to PTC for women and men separately obtained by means of the Harris and Kalmus technique<sup>2</sup>. The recommended corrections for age and sex<sup>3</sup> did not prove helpful at this level of analysis, for, in spite of some smoothing of the curves, the antimode zone remained unaltered. The proportions of non-tasters did not change either. The total non-taster percentage (3.2) is comparable with that found in other Amerindian populations<sup>4,5</sup>. The proportions of non-tasters among the three types of thyroid gland forms (Table 1), given by only five subjects, are not significantly different if tested for independence ( $\chi^2_{(2)} = 0.668$ ;  $0.70 < P < 0.75$ ).

Other results should be compared with the present ones. A significant association has been shown between endemic goitre and the frequency of non-tasters to PTC in a recent survey made in Israel with children of Ashkenazic origin, 8-18 years old<sup>6</sup>. This correlation was not found in a

Table 1. MORPHOLOGY OF THYROID GLAND AND PERCENTAGE OF NON-TASTERS IN 158 PEWENCHE INDIANS

	Women		Men		% of non-tasters
	No.	%	No.	%	
Normal thyroid	6	6.8	20	28.6	3.8
Diffuse goitre	33	37.5	26	37.1	1.7
Nodular goitre	49	55.7	24	34.3	4.1
Total	88	100	70	100	3.2

Table 2. TASTING THRESHOLDS TO PHENYL-THIO-CARBAMIDE IN 158 PEWENCHE INDIANS DIVIDED ACCORDING TO SEX

	Solutions														Total	% of non tasters		
	<1	1	2	3	4	5	6	7	8	9	10	11	12	13	14			
Men	3							1	3	5	20	28	8	1		1	70	4.3
Women	1		1					3	10	26	31	13	2	1			88	2.8
Total	4		1					1	6	15	46	59	21	3	1	1	158	3.2

population of White and Negro-Mulatto boys of the same age in Brazil<sup>7</sup>. On the other hand, sporadic goitres of various kinds have been shown to be related to the non-taster character in repeated observations made in English people<sup>8,9</sup>. Such relationships, for both endemic and non-endemic goitre, appear to be conflicting, as was shown by Fraser<sup>10</sup>.

While our subjects are not comparable with those from Israel from the point of view of age and race, perhaps the main difference is that ours come from a genetical isolate whose inhabitants have been submitted to selective goitrogenic influences for many generations. If this were so, part of the observed variation in the thyroid gland response in endemic goitre zones might be better explained by other factors of population structure in addition to the specific PTC genes effect.

Relationships of the PTC trait with tuberculosis<sup>11</sup> diabetes<sup>12</sup> and paralytic poliomyelitis have been explored<sup>13</sup>. Although some authors have not found the first two associations<sup>8,14</sup>, these results could reflect the simultaneous operation of multiple selective factors. That the PTC polymorphism is unstable is clear from a recent analysis on the White to Negro gene flow in the United States<sup>15</sup>. In most of these investigations the impact of recent immigration is apt to conceal the slower dynamics of a selective factor or to create the false impression of an association.

We thank Prof. Danko Brncic and Dr. Susi Koref Santibañez for their advice. The work was supported by International Atomic Energy Agency research contract 189/R1/OB and by Comisión de Ayuda a la Investigación Científica, U. de Ch., Chile.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, March 8

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 4.30 p.m.—Annual General Meeting. 5.30 p.m.—Dr. Mary Hesse: "The New Problem of Induction".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Prof. Peter Scott: "The Population Structure of Australian Cities".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. H. E. M. Barlow, F.R.S.: "Screened Surface Waves and Some Possible Applications".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. T. Barnard: "Micro-paleontology; Past, Present, and Future".\*

SOCIETY OF CHEMICAL INDUSTRY (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. H. M. Stanley: "Some Achievements in Petroleum Chemicals" (Seventh Castner Memorial Lecture).

## Tuesday, March 9

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. E. H. Thompson: "What is Photogrammetry?"\*

UNIVERSITY OF LONDON (at the London School of Economics, Houghton Street, London, W.C.2), at 5 p.m.—Prof. P. E. de Josselin de Jong (Leiden): "Modern Trends in Social Anthropology in Holland". (Studies in Social Anthropology, 1.)\*

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mrs. Graham Spry: "The Expeditions of John Palliser, Explorer of Western Canada, 1847-1861".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. B. A. Berdal and Mr. K. G. Kiel: "Skogfoss Hydroelectric Power Station".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. F. J. Wilkins, Mr. T. A. Deacon and Mr. R. S. Becker: "A Multijunction Thermal Converter—an Accurate d.c./a.c. Transfer Instrument".

INSTITUTION OF THE RUBBER INDUSTRY, LONDON SECTION (at the National College of Rubber Technology, Northern Polytechnic, Holloway Road, London, N.7), at 5.30 p.m.—Mr. P. McL. Swift: "Oil Extension of Natural Rubber"; 7 p.m.—Dr. D. C. Blackley: "Aspects of the Science and Technology of Rubber Latices—Some Recent Developments of Current Interest".

PARLIAMENTARY AND SCIENTIFIC COMMITTEE, GENERAL COMMITTEE (in Committee Room 6, House of Commons, Westminster, London, S.W.1), at 5.30 p.m.—Discussion on "Developments in the Field of Medical Engineering" initiated by Dr. E. G. Melrose and Dr. S. R. Montgomery.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Sir Lawrence Bragg, O.B.E., F.R.S.: "Waves". (Afternoon lecture for Sixth Form Boys and Girls in Schools from London and the Home Counties. To be repeated on March 10, 16 and 17.)

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. R. A. M. Case: "Demography and the Cancers". (Last of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)\*

UNIVERSITY OF LONDON (in the Manson Lecture Theatre, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. G. N. Jenkins: "Recent Trends in Dental Caries".\*

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. V. E. Gough: "Tyre and Vehicle Vibration".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Brighton College of Technology Chemical Society, at Brighton College of Technology, Lewes Road, Brighton, Sussex), at 7 p.m.—Prof. J. A. V. Butler, F.R.S.: "Nucleic Acids".

## Tuesday, March 9—Thursday, March 11

INSTITUTE OF METALS (at Church House, Great Smith Street, Westminster, London, S.W.1)—Spring Meeting.

## Wednesday, March 10

INSTITUTE OF NAVIGATION (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 3 p.m.—Meeting on "The Economics of Automation".

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W.3), at 5 p.m.—Dr. K. F. W. Hinson: "Lungs and Asbestos".\*

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Dr. T. F. Gaskell: "North Sea Exploration".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. G. King: "Electronic Circuits—Past, Present and Future".

SOCIETY OF INSTRUMENT TECHNOLOGY (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. E. S. Forster: "Industrial Applications of Thyristors (Silicon Controlled Rectifiers)".

UNIVERSITY OF LONDON (at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2), at 5.30 p.m.—Dr. A. R. Ten Cate: "Histochemical Techniques in the Study of the Cellular Biology of Dental Tissues". (Last of three lectures on "The Scientific Basis of Dentistry" organized by the British Postgraduate Medical Federation.)\*

INSTITUTION OF ELECTRONICS AND RADIO ENGINEERS, ELECTRO-Acoustics GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Mr. F. H. Brittain: "Problems in Listening".

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. D. R. Newman: "Aerodynamics and Performance Demands on Aircraft Engineering" (James Clayton Lecture).

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (at the School of Pharmacy, Brunswick Square, London, W.C.1), at 6.30 p.m.—Eighteenth Conversation.

OFFICE OF HEALTH ECONOMICS (at the Royal Society of Health, 90 Buckingham Palace Road, London, S.W.1), at 8.30 p.m.—Mr. S. C. Jones: "Government Relations with a Research Based Industry".\*

## Wednesday, March 10—Saturday, March 13

ROYAL SOCIETY AND THE GENETICAL SOCIETY (in the Botany Lecture Theatre of the Biological Sciences Building, University College, Gower Street, London, W.C.1)—Symposium on "From Mendel's Factors to the Genetic Code".

## Thursday, March 11

BRITISH JOINT CORROSION GROUP (at the Hoare Memorial Hall, Church House, Great Smith Street, London, S.W.1), at 10 a.m.—Inaugural Meeting. Dr. Ulric R. Evans: "Some Problems Facing the British Joint Corrosion Group", followed by Discussion on "The Influence of Metal Structure on Corrosion".

MINERALOGICAL SOCIETY (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

UNIVERSITY OF LONDON (at the London School of Economics, Houghton Street, Aldwych, London, W.C.2), at 5 p.m.—Prof. P. E. de Josselin de Jong (Leiden): "Islam and Culture Change in South-East Asia". (Studies in Social Anthropology, 2.)\*

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Need or Otherwise for the Provision of Stabilizing Windings on Star/Star Connected Transformers", opened by Mr. A. J. Wakeling.

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Two Point Boundary Value Problems in Control", opened by Dr. C. Storey.

INSTITUTION OF MECHANICAL ENGINEERS, HYDRAULIC PLANT AND MACHINERY GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Gear Pumps Versus Vane Pumps".

## Friday, March 12

SOCIETY FOR WATER TREATMENT AND EXAMINATION (at the Royal Society of Health, 90 Buckingham Palace Road, London, S.W.1) from 9.30 a.m. to 5.30 p.m.—Annual General Meeting followed by a Symposium on "Consumer Complaints".

ASSOCIATION OF APPLIED BIOLOGISTS (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, London, S.W.7), at 10.50 a.m.—Symposium on "The Physiology of Roots".

INSTITUTE OF NAVIGATION (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 5.30 p.m.—Meeting on "Height Measurement in Supersonic Aircraft".

INSTITUTION OF MECHANICAL ENGINEERS, STEAM PLANT GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Steam-Turbine Designer and the Metallurgist".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. F. Bergel, F.R.S.: "Whence and Whither Chemotherapy?"

## Monday, March 15

BRITISH SOCIETY FOR INTERNATIONAL HEALTH EDUCATION (at the Drapers' Hall, Throgmorton Street, London, E.C.2), at 5 p.m.—The Lord Cohen of Birkenhead: "Problems in Health Education".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Irreversible Effects Resulting from Breakdown in Transistors and Rectifiers" opened by Mr. C. F. Drake and Mr. A. F. Newall.

ROYAL INSTITUTION, LIBRARY CIRCLE (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mrs. Alban Caroe (Gwendoline Bragg): "The Royal Institution in Sir William Bragg's Time".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER or an ASSISTANT (qualified to give instruction in the field of medieval philosophy) IN PHILOSOPHY—The Secretary of the University Court, The University, Glasgow (March 13).

LECTURERS (with good academic qualifications in physics, preferably including a higher degree) IN PHYSICS for duties in the University Departments of Surgery at the Royal Infirmary; Practice of Medicine at the Royal Infirmary; Surgery at the Western Infirmary; and Practice of Medicine at the Western Infirmary—The Secretary of the University Court, The University, Glasgow (March 13).

LECTURER IN STATISTICAL MATHEMATICS—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (March 15).

LECTURER or ASSISTANT LECTURER IN APPLIED MATHEMATICS—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (March 15).

LECTURER or ASSISTANT LECTURER IN MATHEMATICS—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (March 15).

TUTORIAL RESEARCH STUDENT IN MATHEMATICS—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (March 15).

LECTURER IN APPLIED MATHEMATICS—The Secretary, The Queen's University, Belfast, Northern Ireland (March 16).

ASSISTANT LECTURER IN THE DEPARTMENT OF APPLIED MATHEMATICS AND MATHEMATICAL PHYSICS—The Registrar, University College of South Wales and Monmouthshire, Cardiff (March 19).

LECTURER (with special qualifications in soil biochemistry and microbiology) in SOIL SCIENCE—The Registrar (Room 22, O.R.B.), The University, Reading (March 20).

ASSISTANT LECTURER or LECTURER (or, in special cases, Senior Lecturer) in MATERIALS SCIENCE—The Assistant Registrar (Establishment), University of Sussex, Stanmer House, Brighton, Sussex (March 31).

CHAIR OF BOTANY in the FACULTY OF SCIENCE of the UNIVERSITY of MALAYA—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London, March 31).

DEMONSTRATOR (honours graduate in zoology, entomology, or agricultural zoology, including 1965 graduates) in AGRICULTURAL ZOOLOGY in the DEPARTMENT OF AGRICULTURAL SCIENCES, School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham (March 31).

CHAIR OF GENETICS—The Secretary, The University, Aberdeen (April 2).

UNIVERSITY LECTURER or DEPARTMENTAL DEMONSTRATOR in PHYSICAL CHEMISTRY—Dr. Lee's Professor of Chemistry, Physical Chemistry Laboratory, The University, South Parks Road, Oxford (April 3).

LECTURER or ASSISTANT LECTURER in PHARMACOLOGY, University of the West Indies—Secretary to the Senate Committee on Higher Education Overseas, University of London, Senate House, London, W.C.1 (April 5).

SENIOR LECTURERS or LECTURERS (3) in FORESTRY in the School of General Studies, Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, April 5).

ASSISTANT EXPERIMENTAL OFFICER (botanist or agricultural botanist) to assist in work on factors affecting the yield of field crops—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (April 15).

RESEARCH STATISTICIAN, SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (with a good honours degree in mathematics or statistics and preferably postgraduate experience and some knowledge of agriculture or biology)—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (April 15).

CHAIR OF PSYCHOLOGY—The Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, 2 (April 24).

ASSISTANTS in CHEMISTRY—The Secretary of the University Court, The University, Glasgow (April 30).

LECTURER (with a special interest and research experience in electrochemistry) in PHYSICAL CHEMISTRY—The Secretary of the University Court, The University, Glasgow (April 30).

ROCHE POST-DOCTORAL FELLOW in PHYSICAL CHEMISTRY, with special reference to crystal and molecular structure studies or organic compounds—The Secretary of the University Court, The University, Glasgow (April 30).

JUNIOR and SENIOR GEOLOGISTS—The Director, Mines Branch, Department of Lands and Mines, Province of New Brunswick, Fredericton, N.B., Canada.

LECTURER (preferably with experience in electronic and microwave physics) in PHYSICS—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

LECTURERS and ASSISTANT LECTURERS in CHEMISTRY—The Registrar, The University, Manchester, 13, quoting Ref. 29/65/Na.

MASTER to teach Mathematics up to advanced level and university scholarship standard (half the teaching at least being with Vith Forms); and a MASTER to teach Biological subjects up to advanced level and university scholarship standard (with a substantial amount of Vith Form work)—The Headmaster, King's College School, Wimbledon, London, S.W.19.

MICROBIOLOGIST (under the age of 30 years and preferably with virological training) in the VIRUS VACCINE DEPARTMENT, to undertake the testing of new immunological products—The Secretary, The Lister Institute of Preventive Medicine, Elstree, Herts.

POST-DOCTORAL RESEARCH FELLOW (preferably with practical experience of N.M.R., or an interest in theoretical calculations) in THE DEPARTMENT of ORGANIC CHEMISTRY, for work on high-resolution N.M.R., with Dr. R. J. Abraham—The Registrar, The University, Liverpool, 3, quoting Ref. CV/47/9/N.

PRINCIPAL LECTURER in POLYMER PHYSICS—Clerk to the Governors, National College of Rubber Technology, Northern Polytechnic, Holloway, London, N.7.

PRINCIPAL LECTURER in ZOOLOGY—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

RESEARCH FELLOW in the DEPARTMENT of MATERIALS, to work in the field of high-temperature deformation in metals—The Registrar, The College of Aeronautics, Cranfield, Bedford.

RESEARCH FELLOW (with a Ph.D. or equivalent research degree with some experience in cryogenics) in LOW-TEMPERATURE PHYSICS to study the effect of high magnetic fields on nuclear and electronic interactions in magnetic metals at very low temperatures—The Deputy Secretary, The University, Southampton.

SENIOR RESEARCH ASSOCIATE (science graduate holding M.Sc., Ph.D. or equivalent qualifications with some experience in protein chemistry) in the DEPARTMENT of CLINICAL BIOCHEMISTRY, for research on isoenzymes in cancer—Prof. A. L. Latner, The Department of Clinical Biochemistry, Royal Victoria Infirmary, Newcastle upon Tyne, 1.

# PRECISION ULTRAVIOLET AND VISIBLE SPECTROSCOPY FOR £815

The Unicam SP.500 Ultraviolet and Visible Spectrophotometer is now available complete for mains operation for £815.\*

This well tried and proven instrument is to be found in laboratories throughout the world where its accurate reliable performance has set new standards.

With the Unicam SP.500 there are no extras required for normal operation—the price includes everything necessary for precision all mains operation, deuterium lamp supply, 115 D power supply and SP.549 internal power unit—right down to four glass and two silica cells in cases and a set of dust covers. In the U.K. installation is free. All you provide is your sample.

Write for the SP.500 booklet today.

## THE CROFT PARALLEL GRINDER

This parallel grinder has been specially designed and constructed for the Palaeontologist.

A Brachiopod or similar fossil is mounted in plaster, and attached to the specimen holder with Cerosene wax. The machine then rotates on three ball bearings on a restricted parallel plane, and the micrometer head, which is graduated in 100ths of millimetres, can be set to grind off a requisite amount.

Through various stages of grinding, the fossil is washed, and the structure recorded by means of drawings, photographs or cellulose acetate peels. Thus the complete internal structure of any fossil can be recorded every 1/8th millimetre, or less if required.

The motor driven version of this machine can also be used for controlled grinding of thin specimens and has been successfully applied to the manufacture of thin sections of teeth, bone and gall stones.

## SCIENTIFIC RESEARCH AND TRAINING IN AFRICA

AT the Lagos Conference on the organization of research and training in Africa, at which some 28 countries were represented, recommendations were adopted outlining a plan for scientific research and training in relation to the conservation and utilization of natural resources. Many of them are unexceptionable; collectively, they appear somewhat unrealistic. There is little evidence that the wise counsel of Dr. S. Dedijer on undeveloped science in undeveloped countries has yet fallen on receptive ears. The Plan\*, as now published by the United Nations Educational, Scientific and Cultural Organization, in association with the United Nations Economic Commission for Africa, will do little to encourage those who have stoutly championed the continuance of the Overseas Research Council and advocated much more generous support from Britain in that field.

First, dealing with national scientific policy, the Plan recommends continued and large-scale efforts by the African Governments to promote scientific and technical research on natural resources. For this purpose systematic campaigns in each country are recommended to direct attention to the essential part which science and technology can play in solving social and economic problems. Also recommended are the mobilization of all possible means to deal with a shortage of scientific and technical staff and the establishment of a true corps of permanent research workers, including the creation or reinforcement of suitable national scientific structures. These Government measures for the exploitation and utilization of natural resources should include measures for conserving both fauna and flora.

The second section of the Plan, dealing with the organization and implementation of policies of research on natural resources, suggests the establishment of appropriate scientific research committees to determine the research objectives, and the budgeting arrangements within the national planning bodies. It recommends, moreover, that neighbouring countries should co-ordinate their research policies in matters of common interest in this field, exchanging information and co-ordinating efforts to facilitate the implementation of joint projects and the joint use of research institutions. Next, it recommends the establishment, at national or sub-regional levels, of specialized institutes for scientific and technical research on natural resources, possibly by the development or combination of existing institutions for this purpose. The number of inter-African documentation centres should be increased at least three-fold. At the continental level, it recommends a Scientific and Technical Committee on Natural Resources in Africa. This Committee would be specifically concerned with: (1) harmonizing the methods, terminology and utilization of basic maps for study and research on natural resources; (2) facilitating comparison between the results obtained in national research programmes; (3) ensuring that national research programmes would be compared as a matter of course in

disciplines where this was essential for the advancement of knowledge, and arranging continental programmes in the earth sciences and life sciences, and establishing relations with the international scientific community in matters of common concern. The African countries are further recommended to note international research programmes and consider how they may support and participate in such programmes as the International Hydrological Decade, the Upper Mantle Project of the International Union of Geodesy and Geophysics, the International Biological Programme, and the International oceanographic research programmes co-ordinated by the International Oceanographic Commission.

The third section, on scientific and technical personnel, proposes to develop the supply of research workers required on a ratio of 1 : 2 : 3 for postgraduates, graduates and technicians, and recommends that Unesco should study the distribution of levels of research workers in the English and French-speaking countries, as well as survey the total number of research workers at present working in Africa. For the period 1965-80 a target of 200 scientific workers and university teachers per million inhabitants is suggested. There are recommendations regarding the development and content of educational systems, including a study of the use of audio-visual techniques for secondary and higher education and of the availability of suitable material. Co-operation between universities and research institutes should include the training of scientists of all levels. The increased part which research institutes could play in this training should be taken into account when considering the expansion of the institutes. On the recruitment and status of scientists, African workers are alone considered, but there is a wise recommendation on the importance of efforts directed to increase the understanding by the general public of the value of the contributions of science in Africa.

The recommendations relating to finance and research economics, set out in the fourth section, include the establishment in each country of a National Scientific Research Council with an appropriate budget and the planning of research projects for at least three years. The present cost of a research team in Africa, consisting of an experienced research worker assisted by a young graduate or senior technician, is estimated at 22,000-24,000 dollars and 50,000 dollars for a research worker with 3 graduate assistants and 2 technicians per year. This section recognizes the value of co-operative research association in certain sectors of the economy as well as the wisdom of encouraging research by private organizations. Criteria are then set forth for determining the national research budget, without implying any order of priority. This contemplates an allocation of some 0.5 per cent of the gross national product to the research sector or 6 per cent of the total investment budget.

The final section on international co-operation is concerned first with the Organization of African Unity and Unesco, secondly with inter-African co-operation and finally with international co-operation. The hope is expressed that Unesco and other international organizations will give technical and other support to the projects

\* United Nations Educational, Scientific and Cultural Organization, in association with the United Nations Economic Commission for Africa. *Outline of a Plan for Scientific Research and Training in Africa*. Pp. 25. (Paris: United Nations Educational, Scientific and Cultural Organization, 1964.) 1 franc; 1s. 6d. See also p. 1165 of this issue of *Nature*.

of the Scientific Commission of the Organization of African Unity. Next, it recommends that each African state should admit Africans of other national states to its institutes or training centres, and that the frequent exchange of professors and research workers should be studied and operated. In view of the shortage of institutions and of personnel, it recommends that arrangements should be made for the geographical distribution of projects among African institutions to avoid duplication of effort. Finally, it 'recommends' that Unesco, the Economic Commission for Africa and other United Nations agencies, inter-governmental and non-governmental bodies, and member states of Unesco outside Africa, should continue to expand their collaboration with African countries in scientific research and training through the provision of scientific and technical assistants.

The *naïveté* of this recommendation is in keeping with the thinly veiled nationalism of the whole Plan and the reluctance to admit the sources of assistance in the past, or the real weaknesses in the present situation which make the Plan so depressing. Fairly enough, the Conference emphasizes that international co-operation must respect the scientific independence of each country, and that action taken from outside should be based on a request from that country, and that all programmes should be related to the National Development Plan if such exists, and be co-ordinated with other efforts in this field. It is equally sound that so far as possible technical assistance of any kind should now be channelled through international agencies such as Unesco or other specialized agencies of the United Nations. Nevertheless, at a time when the financial stability and even the future of the United Nations itself are endangered, and even doubtful, it would seem prudent for the African countries not to desecrate exclusively such channels.

What matters is that these emerging and struggling scientific communities where they exist in African countries should develop their own independent and professional links with the scientific community elsewhere, as Dr. Moravcsik so wisely suggests, and that the Governments of the African countries should consider the full implications of Dr. Dedijs's far-seeing article. Science is unlikely to develop as an autonomous and growing institution in the new states, whether in this field of natural resources or elsewhere, unless the excesses of nationalism are kept, to some extent, in check, and free interchange of scientists and interflow of information are allowed in accordance with proved principles which have stood the test of time in the Western world.

That much appears to be fully recognized by M. S. Adiseshiah in the considered appreciation of this Plan which, under the title "The Planned Development of Scientific Research in Africa", he contributes to *Impact of Science on Society* (14, 137, No. 3; 1964). Apart from scientific manpower, which is the key element, he points out that it is doubtful whether the present allocation to research in Africa even reaches the present 0.2 per cent of the gross national product in India. At the outside it is unlikely that there are more than 10,000 scientists in Africa and the target of 200 scientists per million inhabitants would call for 55,000 in 1970 and 65,000 in 1980. This he regards as within the capacity of the overall educational plan for Africa, but he is emphatic as to the impossibility of carrying out effectively such a plan for the development of scientific research as was proposed at Lagos without the scientific intellectual and financial co-operation of countries outside Africa.

More especially he refers to the challenge to scientists to assist the newly established universities and institutes in Africa and those now being planned, particularly in their staffing problems, and he fully recognizes the part that bilateral scientific assistance is already playing. Here, indeed, Great Britain has special opportunities and has no reason to be ashamed of her contribution, even if its scale and effectiveness might well be increased. Furthermore, M. Adiseshiah emphasizes the need for African countries to establish their own associations of the scientific disciplines federated in the International Council of Scientific Unions and, as the Plan itself recommends, to participate in the major scientific international programmes.

But the development of a scientific community is not easily achieved, and it is sensitive to many influences which could easily halt its advance or even cause it to wither. M. Adiseshiah's doubts and reservations are expressed in the unanswered question which closes his paper: Can a five-fold increase be achieved in Africa in the next 15 years when the rhythm of the industrialized countries shows merely a doubling of scientific activity during the same life-span? Rightly he looks for the answer outside the domain of science and his paper points fairly enough to the political considerations which Dr. Dedijs has so painstakingly outlined.

Some further light on such questions is forthcoming from the further papers: that on "Priorities in Science and Technology for Developing Countries" which Prof. C. F. Powell gave to the twelfth Pugwash Conference last year and which has since been printed in *Scientific World* (No. 3, 1964); and on nuclear power in developing areas, given originally at the United Nations Conference on the Application of Science and Technology for the Benefit of the Less Developed Areas, and summarized in the same issue of the *Scientific World*, and that by T. Kristensen, "The Western Industrialized Nations and Developing Countries", in the *O.E.C.D. Observer* for December 1964. Prof. Powell, for example, reviews briefly the general nature of the problem of science and technology as an aid to developing countries, and makes some suggestions for promoting such development. He is well aware of the tendency in some countries to reject the idea of external assistance and to rely on their own resources. However, while he admits that it is important to emphasize the mutual advantages of technical assistance, he also recognizes that there are often serious political difficulties in the way of granting aid. Above all, any suggestion or implication of charity on the part of the advanced countries must be avoided, as well as the persistence of old colonial attitudes or relations through the work of technical experts. Instead a growing understanding must be promoted of the politically beneficial role of science among the Governments and peoples of the developing countries, as well as the value of science and technology to the developing countries.

Not all these difficulties are well founded, and Prof. Powell quotes W. A. Lewis's observation that in most of these countries it is the will that is lacking and not the means. What is involved is that political leaders should give priority to economic development, at least to the extent of not using the strains created by development policies to attack each other. Other issues are commonly much more exciting than economic development and also more rewarding as possible sources of political power. Quite apart from the effect of tensions arising out of the cold war hindering the proper planning and development

of aid, while it may be an immediate imperative for a new state to support and extend the work of research stations already established for its specialized crops and to develop research in relation to the improvement of agriculture as a first and essential step towards an increasing standard of living, such measures may not be politically rewarding. Education again presents problems which may be even more difficult for a developing country than for an advanced country, and where the universities are concerned this is linked up not merely with the supply of scientists and technologists but with the choice of projects. In a developing country it may be vital to choose those fields of investigation which it can pursue most advantageously, and to avoid following a pattern which may be appropriate in someone else's situation.

That is one reason for scientists in the developing countries becoming assimilated into the world community of scientists, but the mis-application and mis-direction of aid could well be radically transformed by a different climate of international relations. Here it is not only the African States who have something to contribute. Prof. Powell suggests that scientists might help by promoting frank and friendly discussions on the many political and technical problems that hinder large-scale international collaboration for aid. Certainly they could do this by helping to identify concrete problems, and by suggesting approaches to some of the technical difficulties or ways of overcoming them. Prof. Powell believes that an enthusiastic response could be won from the scientific community if it became clear that the great powers were really determined to see that our great scientific resources were employed for human welfare, and he finds evidence that some of the best leaders of the developing countries are receptive to such ideas.

This plea for creative thinking is supported by the whole trend of the paper on nuclear power in developing areas. While the possibility of producing nuclear power on an industrial scale has been demonstrated for several reactor systems, the question of installing nuclear power reactors in the developing countries with limited resources of conventional energy is now becoming one of suitable timing rather than of principle and, as such, involves exactly those considerations which Dr. Dedijer and Prof. Powell have stressed. The best possible investment of large amounts of capital depends on correct timing, and this involves a careful analysis of existing domestic energy resources, of forecasts of future demand for power, and of the costs and alternative means of meeting this demand. It must take into account the long period required to bring a nuclear power plant into operation and the importance of such a plant for the future nuclear power programme of the country concerned.

All this, and the several concrete steps which the article suggests a less-developed country would need to take before constructing a nuclear power station, demands a degree of sophistication of which the Lagos Conference gave little sign and which is unlikely to be fostered in an atmosphere of intense nationalism. The paper by Mr. Kristensen, secretary-general of the Organization for Economic Co-operation and Development, likewise points to the dispassionate atmosphere which is required if we are to contemplate seriously a *per capita* increase in production of 3 per cent a year in the developing countries. This would mean an overall growth of between 5 and 6 per cent compared with the overall growth of 3 per cent which a 2 per cent capital growth in the industrialized countries means. Even so, it would still take some 200

years for the average income levels in the developing and the industrialized countries to become comparable.

But for this to be achieved Mr. Kristensen insists that the developing countries must meet three requirements: they must have more knowledge, more capital, and wider markets for their products. Of the three, knowledge is much the most important, finding the necessary markets being related to knowledge, just as is capital, and in this last connexion he observes that it would be profitable for Western industrial firms to build a substantial part of their plant in the developing countries and export the goods to industrialized countries where wages are higher. Knowledge, however, is the critical factor since the fundamental difference between the industrialized nations and the poor countries lies in the fact that the former have at their disposal the results of modern science and education and the developing countries have not.

Knowledge is here used in the widest sense of technical skill, commercial, agricultural and industrial experience and craftsmanship, with a well-established social order, stable political leadership and experienced administration. To achieve this the developing countries have to extend the store of knowledge in height, in breadth and in depth. Essentially this is a matter of time as well as of correct choice of priorities and wise and firm policy: it may well require two or three generations to improve the educational level and it is a hard task to plan the development of an educational system so that the right sequence is followed. The Organization for Economic Co-operation and Development has already analysed and planned educational development in six Mediterranean countries for the next 15 years and these studies could well help developing countries elsewhere.

Mr. Kristensen next referred to the factors involved in the problem of helping developing countries to solve this problem during the long period before their fund of knowledge was adequate, capital flowed in of its own accord and production adjusted itself automatically to existing markets. The Organization for Economic Co-operation and Development is at present discussing measures which might be adopted to facilitate the export of private capital and to overcome the obstacles created by elements of insecurity, and Mr. Kristensen added that all the evidence indicated that public financial help would also be required to an increasing extent. On export markets he referred to the export of primary products and of industrial goods. He thought it might be possible to organize markets for primary products better and that the advanced countries could help the developing nations to achieve this. Concerning industrial goods he believed that the developing countries would be well able to compete, because of their lower wages, when they had built up their knowledge. On all counts, in the long run, technical assistance was the most constructive contribution that developed countries could make to the developing countries.

This means helping those countries to analyse their own problems and to plan their own development, and in this large task, Britain's contribution to the building up of education is the most complex. Mr. Kristensen recognizes that there are dangers because some discords are almost inevitable while the process of diffusion proceeds, alike of techniques, of science and of economics. Goodwill, mutual respect and trust are essential and without them the Western nations can scarcely provide the leadership and help that are needed. The whole *tempo* of this paper, however, indicates the opportunities as well

as the responsibilities. Certainly it should help to dispel whatever there may have been in the atmosphere of the Lagos Conference which hinders a constructive approach to the immense tasks confronting the emergent countries of Africa, or the full co-operation of scientists everywhere in assisting those countries to discharge these tasks successfully.

## MATHEMATICAL METHODS IN U.S.S.R. TECHNOLOGY

### A Course of Higher Mathematics

By V. I. Smirnov. Translated by D. E. Brown. Translation edited by I. N. Sneddon. Vol. 3, Part 1: Linear Algebra. Pp. ix+324. 63s. net. Vol. 3, Part 2: Complex Variables/Special Functions. Pp. x+702. 110s. net. Vol. 4: Integral Equations and Partial Differential Equations. Pp. xiii+814. 126s. net. Vol. 5: Integration and Functional Analysis. Pp. xiv+638. 126s. net. (International Series of Monographs in Pure and Applied Mathematics, Vols. 60, 61 and 62.) (London and New York: Pergamon Press, 1964.)

THESE volumes complete the translation of Smirnov's massive treatise, which, it must be remembered, was designed with the needs of physicists and engineers in mind. There is a hint in the author's preface to Volume 5 that a further volume on differential operators might be written some day.

One noteworthy fact is that modern algebraic theories are regarded as being as important as calculus and the theory of functions. Volume 3, Part 1, on linear algebra, is a self-contained text on determinants, linear transformations, matrices, quadratic forms and group theory. While the range is practical enough to include numerical illustrations of the reduction of quadratic forms to canonical form, it is abstract enough to deal with the elements of function spaces and Hilbert space, a pointer to the thorough and recondite work on functional analysis in Volume 5.

The classical theory of functions of a complex variable occupies Part 2 of Volume 3. Much of it will serve the young mathematician as well as the technologist, but the emphasis is, very properly, on elaborating the powerful techniques of this theory. Thus Cauchy's fundamental theorem on the integral of a regular function  $f(z)$  is proved on the assumption that  $f$  has a continuous derivative, so that Green's lemma can be used; the possibility of removing the continuity condition is mentioned, but not pursued. The simple mapping theorem is proved, but Riemann's existence theorem for the mapping of a connected domain on a circle is quoted without proof. This, of course, does not hinder a full development of the technique of conformal mapping, including the Schwarz-Christoffel transformation, and sections on applications to electricity and to hydrodynamics (where we have to recognize Blasius's theorem under Zhukovskij's name). The formalities of the residue calculus, and the theory of special functions (Legendre, Bessel, the elliptic functions) balance elegant formalism neatly against practical applications. One unusual feature is a chapter on functions of several complex variables, while one sad one is the use of  $Q_n$  for the Laguerre polynomials.

The main theme of Volume 4 is that of boundary value problems in mathematical physics. Two hundred pages on integral equations of Fredholm and Volterra type, with singular equations of the Cauchy and Fourier character, and 100 pages on the calculus of variations, with the nature of extrema, strong and weak variations, and an excursus which yields the whole of the fundamental theory of linearized elasticity on a variational basis, form a solid foundation for the study of boundary value

problems. In a long chapter on the theory of partial differential equations, characteristics are made the core of the work, and the culminating chapter deals with boundary value problems in ordinary differential equations, with the use of Green's function, and with elliptic, parabolic and hyperbolic partial differential equations, in great detail and thoroughness. Throughout this section, we are constantly brought back to physical problems in electro-magnetism, heat, elasticity. Nothing much is said about approximative and numerical methods; other well-known Russian texts deal fully with these aspects.

Up to this point, the content of this work resembles, for example, that of Sir Harold and Lady Jeffreys' *Methods of Mathematical Physics*, though the Russian book is much more voluminous. But in the final volume, the abstract disciplines may startle the theoretical physicist, and, *a fortiori*, the engineer. Set theory, the Stieltjes and the Lebesgue-Stieltjes integrals, the theory of completely additive set functions belong to quite advanced mathematics; and when this is followed by a detailed study of metric and normed spaces, and of Hilbert space, some readers are going to ask what all this is in aid of. But the general theory of operators, with the theory of functionals as a special case, can scarcely be understood without the concept of an operator as a transformation between elements in two metric or normed abstract spaces. The author obviously owes much to Sobolev's work on the applications of functional analysis to mathematical physics, but even so, this volume is the least satisfactory of the series when it comes to relating the mathematical content to physical problems. Much has to be taken for granted.

Prof. Sneddon, in his introductions to each volume, rightly indicates the high regard in which this major work is held by applied mathematicians of all kinds in the U.S.S.R. In Britain, the engineer and the technologist have, on the whole, been content to rely on the ingenuity and industry whereby they can extract the maximum amount of value out of a comparatively elementary knowledge of mathematics. How long will this suffice? Recently, a panel of mathematicians in the United States made a survey of Soviet contributions to mathematics, and drew the conclusion that the U.S.S.R. is unequalled in its ability to apply mathematical theories to practical problems. They commented on the large number of Soviet engineers who keep up with the latest mathematical developments and exploit the deepest kind of mathematics. If time spent on learning something of the rather more abstract developments of modern mathematics will mean a significant economy of time and effort at the stage of practical application, can we give the young technologist not only the time but also the taste and incentive to make such a study?

T. A. A. BROADBENT

## ELEMENTARY NUCLEAR PHYSICS

### Nuclear Physics

By Irving Kaplan. (Addison-Wesley Series in Nuclear Science and Engineering.) Pp. xiv+770. (Reading, Massachusetts, Palo Alto and London: Addison-Wesley Publishing Company, Inc., 1963, second edition.) 64s.

THERE seems to be a widespread predilection among the writers of physics books to overestimate the capacities and comprehension of the readers to whom their books are addressed. Thus one finds that many undergraduate texts are appreciated and studied in detail only at graduate level while the presentation of graduate texts often taxes the understanding of the experienced professional physicist, and theoretical treatments aimed at the experimentalist all too frequently fall short of their mark. One result of this must surely be the generation of diffidence and despondency in the average reader of such

oks, a result which one hopes is not intentional. It is a pity, therefore, to pick up a volume which is intended as an introductory text-book for the undergraduate and which looks as though it could indeed be read right through to the end with a high degree of understanding by any undergraduate of average ability willing to devote sufficient time to its 700-odd pages.

In writing his *Nuclear Physics*, Kaplan has tried to make it "elementary", "introductory" and "coherent" and seems to have succeeded to a fairly satisfactory extent on all three points. Perhaps too little mathematics is used, but wherever it occurs it is very clear and is at all times supported by sufficient discussion and description. The book is divided into three sections, and since it is intended for students who are not already familiar with quantum mechanics and atomic theory the first section is devoted to "The Background of Nuclear Physics". This provides very readable and assimilable introduction to what is generally referred to as modern physics. The second section covers the basic material of nuclear physics with emphasis in the first few chapters on the historical development of the subject. By the end of this section the reader could be familiar with much of the language of experimental nuclear physics and with a few of the more essential theoretical ideas. The final section deals with more newsworthy topics such as fission, reactors and particle accelerators.

Throughout, the book reads very smoothly and the style is quite informal. The illustrations are excellent and there are abundant references to the original literature. Quite a number of these have been carefully selected so as to be suitable for the kind of student likely to be reading the book. The problems at the end of each chapter are quite simple, mainly of the arithmetical rather than the analytical variety. Their main function will be to give the reader a feeling for the scale of things and to illustrate the kind of sums which the practising experimental nuclear physicist works out every day in his laboratory.

For those already familiar with the 1955 edition it may be stated that the present edition is not very different. It appears to be rather bulkier but this is partly the result of typographical changes. Apart from one chapter which has been dropped, that on isotope separation, the chapter headings remain the same. But new material has been added to them and all the additions are to be commended. There are two new sections on the neutrino and on the non-conservation of parity, several pages on multipole radiation from nuclei, some small additions to the chapter on nuclear reactions and a general expansion of the chapter on nuclear forces and nuclear structure. Several other all additions have been made, such as a section on controlled thermonuclear reactions, and there is slightly more emphasis on mathematical ideas. For example, in the first part of the book a simple solution of the Schrödinger equation is given and this equation is also discussed a little further in the chapter on nuclear forces. Finally, the value of the problems has been greatly enhanced by the provision of detailed answers.

The main sins of this book are sins of omission. In places it is slightly out of date, despite the revisions. For example, there is no mention of semi-conductor detectors in the section on the detection and measurement of radiation and the description in Chapter 12 of multi-channel differential pulse height selectors is obsolete. It is also regrettable, despite the remarks in the preface, that nuclear moments have not been discussed at all. However, in a book of this length and scope such cutting and trimming are inevitable and the choice is partly a matter of personal preference. It can certainly be strongly recommended for all kinds of students who have an interest in nuclear physics but who are not going to become nuclear physicists. It should be adequate for most students of chemistry, engineering, biology and applied physics and also for the scientific and technical personnel

associated with nuclear research and development. For the student who may eventually pursue research in the subject it can be recommended as a good descriptive introduction, but such a student would very quickly require further material on a more formal level.

W. M. CURRIE

## CONTROL OF NUCLEAR ENERGY

### The Atomic Adventure

*Its Political and Technical Aspects.* By Bertrand Goldschmidt. Translated from the French by Peter Beer. (The Commonwealth and International Library of Science, Technology, Engineering and Liberal Studies.) Pp. xii + 259. (London: Pergamon Press; New York: The Macmillan Company, 1964.) 25s. net.

THIS translation of the second and enlarged edition of Dr. Goldschmidt's book, first published in 1962, is a fitting complement to Mrs. Gowing's subsequent book, *Britain and Atomic Energy, 1939-1945*. He covers a wider canvas, but even the chapter of some 30 pages which covers the same period supplements Mrs. Gowing's account, notably in respect of the French effort. It is interesting to note that Dr. Goldschmidt shows no resentment of the American policy which forced the return home from Montreal and Chalk River of French technicians. It is, in fact, Dr. Goldschmidt's deep understanding of all that was involved, as well as his prescience and wisdom, that give such great value to this discerning account not merely of the development of nuclear energy and its applications but of the wide political and technical implications of these developments.

The first six chapters are chronological: the accounts in the first two of research in radiochemistry, leading to the discovery of fission and the development of the first atomic bombs, are followed by sympathetic accounts of the United States monopoly (1945-49); the race for the hydrogen bomb and the final years of the policy of secrecy (1949-54); the years of optimism (1954-59); and the years of adjustment (1958-62). These chapters are of especial interest for their account of the development of the French Commissariat for Atomic Energy, the industrialization of its programme and the way in which the French Government turned towards the development of nuclear weapons. The account of international collaboration and of efforts at international control, from the early Baruch Plan to the conclusion of the test-ban treaty in 1963, is clear and fair. It provides a balanced picture for the final four chapters, in which Dr. Goldschmidt discusses, successively, the renewal of confidence, nuclear weapons and disarmament, industrial development and the problem of radiation, and the future of nuclear energy.

In the first of these chapters, after describing the renewal in 1962-63 of the nuclear industry, Dr. Goldschmidt gives an interesting account of the French nuclear programme. It is perhaps natural that at this period his references to the position in Britain are not always quite up to date. The discussion of nuclear weapons and disarmament is thoroughly realistic and once again it is emphasized that real international peace is impossible without the creation of a world government or some sort of supra-national authority to which all Powers, without exception, delegate their sovereignty in the field of nuclear energy. The Moscow Test Ban Treaty is set in its proper perspective. The limitations of civil defence are discussed, and the vital importance, at this stage, of adequate nuclear co-operation in the North Atlantic Alliance is well argued.

Nor are all nuclear problems in the armament field. Turning to industrial development, Dr. Goldschmidt dis-

cusses just as realistically the problems presented by radiation and the disposal and treatment of radioactive wastes, which constitute both an additional cost in nuclear power and a physical problem of which the magnitude alone is as yet barely appreciated. To such problems and to the political problems of disarmament Dr. Goldschmidt returns in his last chapter, and here, as throughout the book, it does not need Sir John Cockcroft's preface to indicate that Dr. Goldschmidt writes with the authority of intimate knowledge and experience in the international as well as the national field. His competence is manifest on almost every page and is joined with a felicity of expression, faithfully reproduced in Mr. Peter Beer's translation, that makes for easy and even fascinating reading. The possibilities which nuclear energy has opened up for mankind are soberly and realistically appraised, as are the limitations involved and the price that has to be paid. Nothing short of general disarmament can avert the threat of mass destruction, and to enjoy the benefits of nuclear power and its concomitant advantages of radioactive isotopes man must accept the stern challenge of finding some means to limit national sovereignty and eliminate the threat of war.

R. BRIGHTMAN

## CHEMISTRY AND THE ARTS

### Analysis of Ancient Metals

By Prof. Earle R. Caley. (International Series of Monographs on Analytical Chemistry, Vol. 19.) Pp. xi+176. (London and New York: Pergamon Press, 1964.) 70s. net.

AT first sight there is no reason to believe that analytical techniques applied to archaeology and the arts should differ from the procedures of classical chemistry. However, when the peculiar requirements of the archaeologist and museum curator (such as the fact that no damage may be permitted) are considered, it becomes evident that only certain methods are applicable. Some four years ago Dr. Aitken gave us a book entitled *Physics and Archaeology*, now Prof. Caley fills in the gap admirably and considers what the analytical chemist has to offer to the world of archaeology; unfortunately he limits his book to the consideration of metals alone, and although this is an important aspect, by far the most important conclusions have been reached by the analysis of other archaeological material such as ceramics.

Prof. Caley has had much experience in the analysis of ancient metals, and this has brought him into close contact with archaeologists. In his book he points out the very real problems involved in explaining the significance of results to the non-scientist. We hear much about bridging the gap between the two cultures, but only those actually engaged in the operation can know just how far apart are the two different methods of approaching a problem, let alone the actual ignorance of each other's subject, particularly in the case of the non-scientist knowing the chemist's jargon. Prof. Caley also points out the pitfalls which the scientist must be careful to avoid; in particular the heterogeneity of ancient metals due to corrosion, surface enrichment or previous restoration is discussed in some detail.

The main portion of the book is devoted to describing the methods of analysis best suited to each type of ancient metal object—gold, silver, copper, iron and their alloys are given special attention, while the other metals known in the ancient world, in particular lead and tin, are adequately covered. Both rapid qualitative and accurate quantitative techniques are described on the macro and semi-micro scales. Major, minor and trace elements are covered. The methods described in detail are wet chemical methods, most of which require moderately large samples. It would seem that these are well suited to large metal objects where a small hole into the body of the metal

(to avoid contamination of the sample from corrosion) an unrepresentative sample from surface enrichment would not distress the museum curator. However, to a numismatist in the coin room is quite a different matter; he is particularly fussy, and even the most minute damage to a reasonably well-preserved coin is generally unacceptable. By the number of analyses quoted in his book would seem that Prof. Caley is in touch with an unusually broad-minded museum, and indeed it is entirely rational that limited damage should be permitted to such material if such studies are going to broaden knowledge as a whole.

Perhaps, however, this brings us to a point where Prof. Caley's book is a little weak. Essentially non-destructive methods are important and little space is given to them. Although considerable space is given to the somewhat dubious specific gravity method of assay of gold and silver objects, no detailed description of neutron activation X-ray fluorescence is provided. Recent advances in the techniques obviate some of the objections raised by the author against them. For example, the advent of the milliprobe X-ray spectrometer which uses a 100 fluorescent source and bent crystal geometry spectrometer means that the disadvantages of awkward shape disappear and the errors inherent in surface enrichment may be prevented by scraping a minute area. Also some objection to neutron activation and  $\gamma$ -ray spectrometry has disappeared since the advent of lithium drifted silicon detectors where the resolution of spectrometers has been improved some ten-fold. The use of emission spectrometry has, on the other hand, been given adequate space and short descriptions of the most useful methods are given.

The book ends with an excellent chapter on the preparation of reports, attention being directed again to the special problems involved in writing for non-scientists. Some indication is also given of the type of conclusion which may be drawn from analytical results. Explanations of external appearance, methods of manufacture in the ancient world, evidence of trends in economic conditions and detection of forgeries are all subjects which may be forwarded by this type of investigation.

However, one of the objects of analysis is often to trace the provenance of metals and to try and find evidence for trade between different communities. The evidence quoted in this book for such tie-ups only strengthens the belief held by many people that in the case of metals or very rarely are such archaeological conclusions possible. Because of the crudeness of the smelting operations, and the practice of remelting scrap, the composition of even closely related objects is very variable. E. T. HALL

## ADHESION AND THERMAL DEGRADATION OF HIGH POLYMERS

### Autohesion and Adhesion of High Polymers

By S. S. Voyutskii. Translated from the Russian by S. Kaganoff. Translation Editor: V. L. Vakula. (Polymer Reviews, Vol. 4.) Pp. xiv+272. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1963.) 115s.

### Thermal Degradation of Organic Polymers

By Samuel L. Madorsky. (Polymer Reviews, Vol. 4.) Pp. xiv+315. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1963.) 94s.

THE books by Prof. S. S. Voyutskii and Dr. S. L. Madorsky have certain aspects in common. In other volumes in this series, they are concerned with fields of polymer science which are in process of rapid development. Both subjects have important scientific and technological implications. Application of basic principles

polymer science has led to a better understanding of the nature of adhesion and to the development of synthetic adhesives which are often markedly superior to natural ones and with a widening range of applications. Studies of the thermal degradation of high polymers are important not only theoretically but also in relation to the development of polymers of improved heat stability, in problems of flame-proofing and in the selection of materials designed to protect others from the high temperatures encountered in space-flight. In this series of reviews authors are encouraged to speculate and to present their own views and theories. Both books therefore reflect the personal views and work of their authors to a greater extent than most review monographs.

Almost half Prof. Voyutskii's book is concerned with cohesion—coherence between two contiguous surfaces of the same material. Methods of determining the magnitude of this effect and its interpretation in terms of diffusion precede consideration of the major scientific and technological factors affecting it. Film formation from dispersions of polymers is discussed at some length and consideration of welding of thermoplastic polymers includes the effects of variations in pressure, temperature, time and thermal treatment. The remainder of the book is mainly concerned with what the author terms 'specific adhesion', that between adhesive and bonded surface. Critical consideration of methods of measurement is followed by theoretical aspects including theories of adhesion. Factors affecting adhesion are discussed and the effects of surface treatments. Methods of measurement and theories of polymer-metal adhesion are critically discussed. A final chapter deals with tackiness of polymer emulsions and their ability to give long liquid threads under certain conditions. Emphasis throughout is on interaction between adhesive and substrate and some aspects, such as examination of the forces involved in adhesion and mechanical adhesion, involving penetration of adhesive into the pores of the bonded material, receive little attention. This is deliberate, as is pointed out in an introduction. Interpretation is largely in terms of the author's diffusion theory, permitting a unified approach to the problems of bonding of polymers. Perhaps because of the time required for translation there appear to be no references later than 59.

Dr. Madorsky is largely concerned with experimental investigations of thermal degradation. He points out, at the beginning, that knowledge of molecular weight changes, the products of degradation and of the rates and activation energies of the processes concerned, are essential to full understanding of mechanisms of degradation, and describes the apparatus and methods by which such information is obtained. Thermal degradations, over a wide temperature range, of polystyrene polymers, polyolefins, fluorine- and chlorine-containing polymers, polyvinyl acetate and polyvinyl alcohol, acrylate polymers, acrylic polymers, polymers from butadiene, polyisoprenes and neoprene, polyethers, celluloses, polyamides, polyethylene terephthalate, polybenzyl and poly-*p*-xylylene, and phenolic resins are considered in successive chapters. The effects of impurities and of variations in chemical and stereochemical constitution and in molecular weight on degradation products, kinetics and energetics are early described and illustrated and possible mechanisms are critically discussed. A final summary uses the temperature corresponding to 50 per cent weight loss in 40–45 min as a measure of thermal stability and discusses structural and other factors which affect such stability. Dr. Madorsky admits that he has leaned to a large extent on results obtained by himself and his associates at the S. National Bureau of Standards. These account for roughly half the total references, some of which are to papers published in 1963 and 1964. References to relevant work by other authors seem sometimes to be absent and none of the newer polymers of relatively high thermal stability are not considered.

Omissions and restricted treatments of certain aspects in both books are generally deliberate, reflecting the opinions or inclinations of the authors. They detract little from the value of these books, both of which, within their scope, are valuable reviews of rapidly developing fields. Both contain a wealth of experimental data of great interest to polymer scientists and technologists.

W. R. MOORE

## WHAT IS PARASITOLOGY?

### General Parasitology

By V. A. Dogiel. Revised and enlarged by Yu. I. Polyanski and E. M. Kheisin. Translated by Z. Kabata. Pp. ix + 516. (Edinburgh and London: Oliver and Boyd, 1964.) 105s.

TO librarians and administrators short of time, who merely want to know whether they should purchase this book for a zoological library, my advice is to buy. It is an excellent book of its sort; it provides an introduction to the considerable Russian contribution in this field; it will remain useful for many years; by current standards it is good value.

To those concerned with parasitology, the advice is the same; but more must be said to support it, for several books in this field have appeared recently and neither time nor money nor shelf-space will stretch much further.

There seem in general to be two views about parasitology: that it is the study of parasites; that it is the study of parasitism. The first is the majority view, judging from the literature; but is usually taken to mean the study of some parasites, not of all. In one zoological library, 38 works, plus variant editions and translations, are classed under this heading. Twenty-two of them describe some of the protozoa, the trematodes, the cestodes, and some of the nematodes, as so many types in a zoological text-book. Several go so far as to include blood-sucking flies, lice and ticks, as being vectors of disease. A few others cut across this arrangement and deal with the physiology or ecology of parasites or the pathology of hosts. But thirty-one are virtually restricted to parasites that attack man and domesticated animals. If the contents of these books define parasitology, the conclusion is unavoidable that it is a professional subject related to medical and veterinary practice.

A science is expected to take account of all the evidence, not an arbitrarily selected part. Tracing the distribution of parasitism in the animal kingdom, Dogiel estimates (pp. 43–50) that 65 to 70 thousand animal species are parasites. Of these, 13,500 are protozoa and helminths (including all parasitic forms, not only those on vertebrate hosts); while 45,000 are credited to one order of insects, the Hymenoptera, usually not even mentioned in text-books of parasitology. Of course the ichneumon-wasps are not the concern of medical and veterinary practitioners, but are they not the concern of biological scientists?

Dogiel's book represents the other view of parasitology, and is about the phenomenon of parasitism as a whole. Its four main parts deal with parasitism, its distribution and origin (100 pp.); adaptations of parasites (140 pp.); the parasitic fauna and its environment (160 pp.); host-parasite relations (65 pp.). The first of these surveys the parasitic mode of life throughout the animal kingdom and, by grouping its various manifestations in categories, makes possible some interesting comparisons. This is an excellent review, and could be read with advantage by any zoologist.

In the second part, on adaptations in structure and life-cycles, the author sometimes goes too far in trying to be all-embracing. It is difficult to see what of value can be said in one page on the nervous systems, and less than a page on the excretory systems, of animals belonging to several phyla; and the attempt leads to statements that

are not acceptable. But if a few pages were better out, most of the material is excellent, especially that in Chapter 10 dealing with reproduction, life-span, and adaptations of the life-cycles of parasites to their hosts.

The third part is that for which the book is most useful, and indeed indispensable. Any work on the phenomenon of parasitism must of necessity deal with the relations between the parasite and its host. That these are ecological in nature has long been recognized by parasitologists in several countries, but the Russian workers have especially developed this approach. Dogiel follows Pavlovski in distinguishing two environments of parasites: the host, their immediate habitat, constitutes their micro-environment; but they are also affected by the external environment of their host. Much of the material and some of the ideas discussed in this part of the book will be new and illuminating to many western students.

The final part, on host relations, is less satisfactory, probably because Commonwealth and American investigators have contributed greatly to this subject, and Dogiel's account shows him to be unaware of important work published in English. The division of the bibliography into two parts, Russian and the Rest, affords a convenient survey of Russian publications, but is a nuisance in tracing references from the text.

On the whole, then, this book is strongly recommended. It has failings besides those mentioned—the parasitic insects are scurvily treated and their names are often misspelt—but it is a valiant and generally successful attempt to survey a very large field. If it became widely used in courses on parasitology there would be hope of attracting more and better students to this branch of science.

GEORGE SALT

## ORIGINS OF CRIMINALITY

### Crime and Personality

By Prof. H. J. Eysenck. (The International Series in the Behavioural Sciences.) Pp. xv+204. (London: Routledge and Kegan Paul, 1964.) 25s.

PROFESSOR EYSENCK is already well known for his important contributions to the analysis of neurotic behaviour. A tough-minded, behaviouristic approach, a certain impatience of received doctrine, and a manifest contempt for the *mystique* of psycho-analysis have earned him bitter criticism from the traditionally minded. But it would be idle to deny the fertility of his bold, simple theoretical arguments in generating hypotheses that have made their impact in several areas of psychology. In his new monograph Eysenck turns his attention to criminal behaviour—another field in which dynamic theories have long held great and rather ill-deserved prestige. The basic structure of his theory of criminality, and the style of discourse which he adopts, are familiar; one may confidently look forward to another outburst of protest. But like his earlier work it contains some incisive thinking, and will undoubtedly stimulate some interesting research in an area in which new ideas are something of a rarity.

The core of Eysenck's theory is the proposition that conformity with social rules and proscriptions is normally secured by a system of aversions which have been acquired by a process of associative conditioning during the early years of life. Childish pilfering, for example, is generally visited by punishment or some other anxiety-arousing token of parental disapproval; the association between the action (or the contemplation of it) and this unpleasant state of emotional arousal persists and is generalized to the extent that it will be revived by any situation which involves the property of others. Thus the individual exhibits a strong tendency to avoid any behaviour which he recognizes as belonging to the category

'stealing'. Such aversions are—according to Eysenck—powerful, reflexly automatic, and highly resistant to extinction. In normal people they are organized into functional system which constitutes the mechanism of what is commonly termed 'conscience'.

The conception of socialization has several important implications. It represents a rejection of the assumption long cherished in the courts, that social behaviour governed by the anticipation of satisfaction and the dread of punishment—a belief conspicuously at odds with the experience of penologists. Eysenck argues that what causes ordinary men and women to avoid crime is not fear of being apprehended (which, in view of the low detection rates for many types of offence, would in any case be irrational) but the resurgence of anxiety which accompanied similar actions in the past. The peculiar permanence of such conditioned reactions is attributed to the special circumstances in which they are acquired. Social training normally proceeds by partial reinforcement (that is, by irregular pairing of the deed and the sanction), a state of affairs known to result in most effective learning. Moreover, it has been established by experiments with animals that avoidance responses are highly resistant to extinction, presumably because they have the effect of steering the organism away from any opportunity for testing the appropriateness of the anticipatory fear-principle which has been invoked to account for the persistence of phobias and neurotic anxieties.

Why, in the case of criminality, is this mechanism ineffective? The theory proposes three complementary explanations. First, the individual may be constitutionally unresponsive to conditioning. Eysenck asserts that the speed of acquisition of conditioned responses and the extent to which they resist extinction are functions of introversion—a personality dimension which appears to be determined to a considerable degree by genetic inheritance. (Eysenck has recently defended this controversial 'conditioning postulate' on the ground that it properly applies only to situations, such as the socialization process, in which partial reinforcement obtains: here he argues, it has been amply vindicated by experiment. Persistent offenders, then, may have inherited a natural insusceptibility to conditioning. On the other hand, socialization may fail because the arrangements for training the child are inadequate—he may lack the care of parents, or he may be brought up in a disorganized household. Thirdly, Eysenck suggests (in the teeth of strong sociological evidence to the contrary) that some families actually train their children in criminal values and habits, after the manner of Fagin.

This is but the kernel of the argument; the author ranges, with characteristic panache and persuasiveness over an immense field—here discussing basic questions of scientific method, there touching on the ethics of punishment. The psychologist reader will discover little that he has not encountered in one of Eysenck's many previous books, but this one is written for the layman and for the ordinary student of criminology; they will find it an entertaining (if unrepresentative) sample of what the psychologist has to offer to the study of crime. In one respect, however, the book is a disappointment. Its discussion of penal methods is curiously sterile. The reason is not difficult to identify. Eysenck is critic of our contemporary preoccupation with environmental correlates of criminality, and naturally emphasizes its biological foundations; unfortunately in doing so he virtually ignores such knowledge as we presently possess of the social context in which crimes are committed and penal treatment—and social training itself—takes place. It is an odd omission in a monograph which will certainly be of great interest to sociologists and which, indeed, offers greater promise of integrating our fragmented understanding of the criminal than most of its predecessors in this untidy field of enquiry.

GORDON TRASLER

## MANKIND AND MACHINES\*

By PROF. M. W. THRING

Department of Mechanical Engineering, Queen Mary College, London, E.1

## The Engineer's Choice

NOBODY can change the past, but the engineer can change the future. The historian, the classicist, the biologist and the archaeologist observe the past, while the biologist, the modern languages scholar and the economist observe the present. The engineer has a choice about the future; he can invent, develop and design machines for the good or for the evil future of mankind. He is not yet fully convinced of this choice and of the moral responsibility that it implies, but he is gradually awakening to his true position.

In order to help him in his choice of machines to invent, it is necessary to call in the aid of those branches of understanding which admit the possibility of there being a purpose of the universe and of man's life in it—philosophy, religion and even politics. I shall take it as axiomatic at a man's most direct knowledge of all is whether he is happy or unhappy. Hence, although human happiness is excluded from the pure sciences because it cannot be measured, it provides the most important criterion of what is good for mankind. Thus the long-term objective of the engineer must be to invent machines which contribute to the increase of human happiness.

To illustrate this we can put some of the machines which have already been invented on a moral spectrum. Teaching machines, machines that help doctors to cure illness, and machines that help the blind and maimed to lead more normal lives, all appear at the top because they increase human potentialities. Machines for torture and for destruction of human life come at the bottom of the spectrum, while in between come machines for travel, communication, agriculture and all the machines that contribute to mankind having a reasonable standard of living without excessive drudgery or working very long hours. Some examples are electric power stations, the machines of the steel industry, cement or brick kilns and plastic-making machines.

These examples are clear enough, but in order to help the engineer to use the small amount of freedom of choice he has, it is necessary to look a little closer into the way in which he can contribute to human happiness in the future.

It is a prerequisite that we must avoid humanity destroying itself in a war. William James, in his *Varieties of Religious Experience*, refers to the need to find a "moral equivalent for war". I believe that the only possible equivalent is to extend the international competition which already occurs in the field of sport into competition in creative activities, especially the creation of objects of real beauty. We could have an arts Olympic every year and the daily newspapers could have two arts pages. The contribution which the engineer can make to the averting of the danger of war is primarily in the field of using his inventive ability to free mankind to spend more of its energies in such creative activities and to solve the food-shortage problems which remain.

Assuming that the averting of a catastrophic war is successful, then the real choice of the engineer lies in the fact that he can concentrate his energies on inventing free different groups of machines which take mankind in three entirely different directions.

The first direction is the logical extension of complete *laissez-faire*—a civilization in which about 75 per cent of the population are working extremely hard and extremely

long hours to give themselves ever more machines to satisfy unnecessary wants (I like to quote the examples of the machine to carry the player around the golf course and a separate car for every member of the family). The remaining 25 per cent are unable to find work and live on a permanent dole, so we can call this direction 'Devil take the ones who cannot keep up with the Joneses, or the affluent society'.

The second future is the planner's dream or the human ant-heap. Everyone is ordered to live in town or country, and towns become vast blocks of identical 'dwelling units'. Freedom to choose the size and shape of your house, the possession of a garden and how you go to work has all disappeared, but everyone is employed (at work for which aptitude tests have 'proved' them best suited) and has a uniformly high standard of living.

The third future is the only one that preserves human dignity and freedom. If mankind decides to ask the engineers to give him this third possible future, the affluent society will change into the creative society. This will be the only genuine democracy in the sense that its basic aim is to give every man and woman the greatest possible freedom to plan and choose their own lives and the education to do this, so that they obtain the greatest possible satisfaction of their creative needs. The only limitation to the freedom of one man will be that he must not unfairly limit the freedom of his neighbour. The profit motive will remain the effective spur to a man to work hard at his career, but its two curbs will be: (1) normal taxation necessitated by the need to give reasonable support to sick and old people and good education to the young; (2) the number of hours of paid work per week has an upper limit decided on a national basis in order to have employment available for everyone of working age. It is this last need which is the key to the advantage of the creative society, since it means that we can harness the routine labour-saving inventions of the engineer to give more leisure to everyone, even the housewife, instead of unemployment. Then education has the immensely exciting duty of restoring the lost satisfaction of creative craftsmanship in the leisure time. This implies a return to the old idea that schools and universities should educate for life as a whole and thus be responsible not only for training people for their careers but also to obtain a real purpose in life out of their chosen leisure activity, and to have a social conscience. Thus they will be taught that they have a duty to the community not only to work for their living but also to serve it with at least part of their leisure time either by teaching their own creative skill to others or by some kind of social service.

Since the beginning of the Industrial Revolution the number of hours in the working week has halved, and engineers can invent machines to halve it again, so that every ten years from now the hours of paid work can be reduced by two or three. Thus machines offer the possibility of replacing the six-day Biblical working week by a four-day week, and the other three days can be filled with the satisfaction of all the skills that are no longer needed for most people's work. Gardening, carpentry, wood carving, silver and copper beating, playing all kinds of musical instruments, painting and sculpture, will all cease to be hobbies of the few, and everyone will have the opportunity to become a skilled amateur at one of them. Fully employed people will have enough leisure and energy to do all the social duties such as magistracy

\* Substance of the Inaugural Lecture delivered on February 19.

and running clubs. The study of the humanities will become a possibility open to all scientists and engineers.

On this third future the maximum possible freedom is left to man, and especially to housewives, to choose the paid work they do and the creative activity for their leisure time satisfaction—the only limitation is that they cannot be paid for more than the statutory maximum number of hours work a week. Since, however, the payment will be at least twice that necessary to support an adequate standard of living for a normal family they can work only half the maximum number of hours if they wish.

I do not need to elaborate this third future here except to say that the engineer must have such a vision if he is to aim to invent those machines which will best serve humanity. Clearly neither complete *laissez-faire* nor complete anti-heap planning offers an acceptable future for mankind and some intermediate solutions along these lines must be found.

One can conclude: (1) The engineer should continue to invent machines which enable human needs to be supplied with fewer man-hours of labour and solve the world food-shortage problem. (2) He should achieve the second industrial revolution and the first domestic revolution by eliminating all routine repetitive work just as in the first Industrial Revolution he replaced human muscular effort by prime movers. (3) The engineer can help those men and women to satisfy their basic creative needs, whose work does not do so, and to satisfy everyone's need for balance between the trained activities of head, feelings and hands in the steadily increasing leisure time which his success with the first two aims provides.

### What is Engineering ?

As my first degree was not in engineering but in physics and mathematics, I dare to attempt my own definition of the work of the university-trained engineer in order to work out the future of the methods of training. This I shall do in the wider context of the engineer's role in shaping the future of mankind which I have sketched in the first section. The engineer is always concerned with inventing, designing and developing new machines that can serve mankind better. He creates the modern equivalent of the slaves and serfs of earlier civilizations. He has to learn to use his emotional brain, that is, his feelings, to enable him to make that creative or inventive leap over the wall of the existing formulation of the problems to be solved, but he has to refuse to be overawed and daunted by them or to admit his personal insufficiency in face of these. He has to use his emotions to bring his mind back over and over again to the fence until at last he finds the weak point in the apparent restrictions and leaps over into a new field.

He must understand with his mind or intellectual brain all the laws of the sciences concerned in his field in such a way that he can use them, not only to show what is impossible, but also to formulate the difficulty so clearly that the solution or way around becomes also clear. This means he must be able to use, for example, Newton's laws of motion with their gyroscopic solid body and their fluid-flow consequences, the laws of thermodynamics, chemical reaction and electrodynamics in a constructive way as tools with which to invent.

Finally, he must be able to use his knowledge of reality through his hands and eyes and body to produce designs which are sufficiently right in regard to size and strength and shape of all those parts which cannot be calculated from the equations of applied science. This the engineer calls by the mystic name 'design', but it is the use of the same body brain that the artist or musician uses as 'technique', the carpenter calls 'craftsmanship', and that we all use to walk or drive a car with when our minds are fully occupied on some other matter, more or less important.

The really creative act in engineering as in all other arts is the sudden coming together of the work of the three brains so that the emotional power generated by the persistent refusal to be defeated, the correct logical formulation of the problem through the intellect and the feeling for the way Nature works through the hand suddenly open up a new field. This experience produces an unforgettable moment of heightened awareness as memorable as those described by Kekulé in organic chemistry (benzene ring) and Hamilton in mathematics (quaternions). Sometimes the field proves fruitful in producing a valid machine of real benefit to humanity at other times snags are found later which are considerable.

This discussion of the human act of creative engineering shows how it is based on an applicable understanding of the laws and differential equations of science. I often visualize useful human knowledge as a tree with the pure sciences as its roots, mathematical and physical understanding of these laws as the trunk and engineering as the branches bearing the fruit in the form of machine useful to man's standard of living and happiness.

An equally useful analogy is to call engineering the bridge that spans the river of ignorance and prejudice that separates the academic pure scientists in their 'Ivory Tower' on the left bank from the practical men of industry with their machinery and products on the right. This provides the idea of a right-to-left traffic of problem from industry to be solved on a more fundamental level and a left-to-right flow of quite new ideas, such as power generation from nuclear fission. One can also regard applied science as the left-hand pier supporting the bridge and technology as the right-hand pier, since the applied scientist solves a wide range of problems approximately from first principles, while the technologist solves a limited range of problems accurately from empirical knowledge.

The briefest definition I can give of the engineer would want to train is "one who uses his logical understanding of the laws of science and his physical experience of solids, liquids and gases to enable him to invent develop and design new machines and products which contribute to human happiness".

### Future of Engineering Teaching

Education is the key to civilization. It is now accepted in all other countries with highly developed industries and in all spheres in Britain, except the educational one that we can only pay for our imports by exporting advanced manufactures in competition with other technologically advanced countries, if the bulk of our brightest young men and women are trained as engineers in the sense I have already defined here, as they already are in these other countries. Britain led the world at the time of the Industrial Revolution because of an upsurge of uninhibited inventive and creative engineers usually with brilliant business partners. Now that the universities have accepted the idea that engineering, and even in some cases business studies, are fit subjects to breach the wall of the 'Ivory Tower', Britain could regain her lead if the schools were enabled to turn out as strong a stream of inventive and creative engineers as that which arose spontaneously 100 years ago. This achievement has three requisites:

(1) Most boys are fully appreciative of the importance and excitement of engineering as a career up until a year or two before they take their General Certificates of Education at Ordinary Level. However, as was shown by the Oxford University Education Department Survey there is undoubtedly a tendency for the schools to steer those who have the highest marks in their science and mathematics papers into the pure science departments of the universities. While it is quite true that many of the most inventive and creative youngsters are already entering engineering schools, we must also have a bigger

proportion of those who obtain the highest marks in their Advanced Level science subjects, if Britain is to avoid the disastrous failure in the competitiveness of its exports that the whole luxury of an educational system will break down. Hence the true needs of Britain for brilliant creative engineers must penetrate to schools very quickly. I have often been accused of exaggerating when I expressed this view in the past, but the recent trend in our balance of payments is beginning to convince me the diehards that they are fiddling while Rome is burning.

(2) An equally dangerous form of snobbishness exists within the 'Ivory Tower' of the university, where engineering is still often looked on as an inferior intellectual discipline. There are various reasons for this; some of them date back to the delegation of manual tasks to slaves in the Greek and Roman civilizations and others to the upsurge of successful engineering business men from outside the universities who achieved the Industrial Revolution. The truth, in fact, is entirely the reverse, cause the engineering education requires more balanced development of all three brains than any other type of academic discipline. The engineer must learn: (a) how to understand and use the logical intellectual concepts of pure science and mathematics; (b) the emotional aspects of human relations including verbal and written communication of difficult ideas to laymen and of inventiveness; (c) the skill with the hands of the craftsman and the experimentalist. The idea that a man who works merely with his head is superior to one who works both with his head and his hands is not only nonsense but it is dangerous nonsense, since it frequently leads to nervous breakdowns and other consequences of lack of balance. I have written of the two cultures, literacy and illiteracy, as if they were isolated cultures. I believe that there are three cultures corresponding to a man's three brains: (1) literacy corresponding to human relations and hence to the emotional brain; (2) numeracy, logic, mathematics and the laws of pure science, that is, the intellectual brain which works with concepts; (3) which can be called craftsmanship, technique, experimental skill, manual dexterity, which corresponds essentially to trained skill with the body and brain, and especially with the hands. A truly educated man is a man who has trained skill in all three brains. The man who says cheerfully, "I cannot knock a nail in", is admitting just as serious a deficiency in his education as the man who says, "I cannot do mental arithmetic", or, "I cannot spell".

(3) It is often said that when the universities do train good creative engineers, industry is not sufficiently definite in its desire for them and does not give large enough rewards to them to justify the effort we have made. There have even been extreme cases of firms deliberately delaying their creative engineers to make sure that their new developments do not upset routine production in the works. This is another example of Britain's habit of not seeing the writing on the wall until her back is up against it. The more backward firms will have to copy the more enlightened ones who are constantly asking their creative engineers when the new process or project will be ready to go into manufacture.

So far as the schools are concerned, I think the most helpful suggestions would be regular lectures on careers in engineering, given to the science sixth-formers of the schools by industrial enthusiasts, university engineering professors and officials of the newly formed Council of Engineering Institutions. The introduction of prizes for essays in applied science and an Advanced Level subject called applied science which would be the logical lead to all branches of engineering when taken alongside mathematics, and thirdly, small final year projects requiring inventiveness, would all help very much.

The change of mind in industry can only be forced on by the problems of direct competition in export markets

against goods manufactured in other countries, since the habit into which many firms have fallen of paying royalties abroad for all their new developments obviously does not put them into a strong competitive position with the firms from which they are buying the developments. Industry can, of course, also help very much in the schools, by giving really interesting vacation projects to younger science masters.

Obviously my main theme in this section must be concerned with what the engineering departments of the universities can do to change this nationally disastrous trend. First and most important, they must become a much stronger bridge between the universities and industry. This implies strong support for the research projects in the engineering faculty by industry. This is particularly valuable both because it makes sure that research is carried out in potentially fruitful directions and because it gives the research students a feeling of the urgency and importance of their work. Secondly, the Continental system of professors extraordinary would help. In this system a senior industrial engineer or research manager is employed one or two days a week as a professor or lecturer in the engineering department. This system is of immense benefit, particularly to the undergraduate teaching, as it ensures a real up-to-dateness in the courses. It also makes it possible for the practical work of the undergraduates to include some really fruitful brief studies in industry.

Thirdly, the university engineering departments have a big part to play in the upgrading of the status occupied by engineering in the schools and the general public. The creation in Great Britain of the Council of Engineering Institutions with its concept of a chartered engineer will help in this direction, but we also need some method of giving greater public recognition of distinguished engineers. The American announcement on December 11, 1964, of the formation of a National Academy of Engineering shows how the United States has met this problem. Its members will be elected in recognition of: (1) important contributions to engineering theory and practice, including significant contributions to the literature of engineering; (2) demonstration of unusual accomplishments in the pioneering of new and developing fields of technology (see *Nature*, 205, 129; 1965).

The most important problem of all for university engineering teaching is how to encourage inventiveness. There is always a danger that the principles of applied science will be taught in such a way that they become 'postulates of impotence', that is, simply statements of what cannot be done instead of being aids to creative thinking. I think in this connexion it is very important to give all engineering students, very early in their university course, a free-roaming speculative talk about some of the machines which may be developed during their 40 years as practising engineers. This applied science prophecy can be based on the needs of humanity to eliminate from life dullness, drudgery, danger, disease, discomfort and fatigue. One can even go so far as to suggest that there should be some kind of Hippocratic oath for engineers that so far as possible they will direct their invention of machines towards these directions. If this introductory lecture is well enough done, much of the theory they learn later in the course can be illustrated not only in terms of existing machines but in its application to the possibility of the proposed machines.

I am sure that a definite encouragement to inventiveness in the third year of the engineering student's course is absolutely essential if we are to turn out really creative engineers. The third-year project can be made completely inventive and to involve the design and construction of the invention. In the practical class of my final year physics course at Cambridge I was given freedom to suggest and design any experiment I liked. This produced a tremendous impression on me, and I can still remember the details of three, an experimental transformer with a

variable iron core, a bench-scale model of a machine to produce a high transitory magnetic field, and an experiment on the torsion of lead strip.

Some very valuable teaching films have already been made in the United States, and my department at Sheffield produced a number of 10-min films illustrating particular fields of research which I have shown all over the world. The use of 10- or 20-min films as part of the lectures and also to give the necessary material at the beginning of a practical class can contribute greatly to the excitement and interest of the engineering students. It is our most important task to arouse this excitement in the many students who are perfectly capable of passing examinations at the present standard if it is aroused. Production of such a film has many advantages since the member of staff who makes it can put more careful production and rehearsal into it if he knows that the same film will be shown over and over again. It also means that there can be close-ups of demonstrations and pictures of industrial plant illustrating the principles so that theory and practice can be brought much closer together. The use of the films also means that the energy of the lecturers can be concentrated on the period after the showing of the film and much more time can be spent on questions and answers if the theory is given in a carefully prepared concise form. A film on an experiment can be shown 20 or 30 times a year to the students who are about to do that experiment, which would be a quite unfair repetition to ask of a lecturer.

Prof. Boris Ford, in an article in the *Sunday Times* (London) last year entitled "Why so Many Failures?", showed that certain universities have consistently higher undergraduate failure rates than others and that it is not correlated with the level of entrance standards at all but that it correlates closely with the amount of individual teaching received by the students. The optimum number in a group of students receiving such teaching is open to discussion, but the number of hours teaching required makes it difficult to have smaller groups than about three. It is my personal view that while larger groups may prove just as fruitful, the smaller grouping has an informality and therefore a freedom for the student to bring up his difficulties which is bound to disappear in the larger groupings. In any case, Prof. Ford's analysis shows that the old-fashioned view that a student was a born pass or failure or honours man is complete nonsense and that improvements to the teaching method can yield a substantially lower failure rate at the same time as the university percentage intake is increased. As a parent of children of university age, I know just what the possibility of failure means in human terms, and undoubtedly the introduction of these personal teaching schemes is a vital necessity in engineering teaching. Incidentally, it provides yet another reason why the teaching of engineering to undergraduates cannot be carried out successfully unless there is a strong postgraduate research school, since the postgraduates are the ideal people to understand the difficulties that the students are finding with their lecture material, and thus the postgraduates are the right people to do this personal teaching.

The diehards on all university senates spoke of 'scraping the barrel' when we increased our university intake from 4 to 5 per cent of an age-group in spite of the fact that all other highly civilized countries have more than 10 per cent. How an increase of intake at the extreme top end Gaussian distribution can be called scraping the barrel I have never been able to see.

#### Machines of the Future

Since I have already stated it is axiomatic that the engineer has some choice in using his talents in various directions, I think it is useful at this stage to expand a little on the kind of machines that he can develop within the next generation once he has really made up his mind

how he can best help humanity. To take two extremes he could spend the whole advanced research facilities (the world on space travel and landing a man on the Moon or the planets and getting him back again alive) or, at the other extreme, with no more engineering effort he could almost completely eliminate drudgery and food shortage from human life in the whole world. Put in this way, the best choice for the benefit of mankind is obvious and yet curiously enough the kind of money being spent in the world as a whole on advanced engineering research on the first of these two objectives is considerably greater than on the second. Let us suppose that mankind come to its senses and decides to concentrate effort on the most beneficial objective of these two. There already exists in the United States a one-armed robot which can do 200 repetitive movements handling objects weighing up to 75 lb. This machine can put its hand into a red-hot furnace and take out fired materials or place materials in special machines for various types of operation and remove them and pack them afterwards. Another machine available in the United States can move across the floor of a large room wherever the obstacles are located and scrub or clean the floor around the obstacles. I have myself made a number of simple robot hands with micro-switches enabling them to locate objects by touching or to close on to an object whatever its size.

The next stage in the development of robots which will take over the routine operations in the home or the factory is the refinement of sense impressions from these simple micro-switches giving tactile sensation into something capable of recognizing shape and position by means of light and even perhaps colour. The Americans are also developing machines in which the skill in movement of man is amplified in power and speed so that a two-legged device with a man inside can walk at 30 miles an hour across the country with legs 30 ft. long. Thus the various component parts necessary for the complete robot are nearly all available when one includes also the ability of computers to take decisions and operate according to the results of various types of signals. Within the next generation it will therefore be possible to make a robot which can have the equivalent of a logical intellect making decisions according to rules built into it and a reasonable degree of dexterity in operating its hand and self-mobility. The robot will, however, never have the emotional brain of a human both because we do not even begin to know how to develop a machine which could make value judgments, and even if we could, we would not do so since the great advantage of robots is that we can build into them logical decisions based on the best value judgments that man can make. These robots will not only eliminate completely all routine operations and drudgery from human life but also will be able to carry out dangerous operations such as putting out oil-well fires, rescuing human beings from buildings or aircraft on fire, or mending machinery at the coal face so that it will no longer be necessary for human beings to enter the mine at all.

A problem in connexion with the elimination of drudgery which is often raised is the way in which people of low average intelligence will be able to contribute in their working time. Such people often can make the best use of their leisure time by creative manual skills such as gardening, but the solution so far as their contribution to the standard of living is concerned is already suggested by the methods developed in the United States Forces for training such people to diagnose faults and repair them in standardized electronic equipment. They could in fact, be the specially trained repairers of the robots.

Another field in which the engineer can make an immense contribution in the next generation is in communication by films and education. We can already see the possibility of putting the whole of the *Encyclopædia Britannica* on to a few ounces of micro-film together with a viewer which can be carried in the pocket. Methods of

toring information even more extensive than that in the *Encyclopædia Britannica* in such a way that it can be ed in and instantaneously retrieved in verbal form can be developed. The language problem can be completely solved in a similar machine which everyone can carry when communicating with foreigners which converts his speech into some machine language and the machine language back into his speech. Thus an Englishman has only to plug his machine to a Chinaman's and they can talk freely, each receiving replies in his own language. The development of a recording tape which can be read by eye as well as being convertible to sound to the ear is also a straightforward engineering problem. I do not think, however, it will be possible to produce teaching machines which really find out what are each student's difficulties, so that it would always be necessary to have a fair amount of teaching in small group discussions with live teachers, but I think the lecture to a large audience as a means of communicating ideas and theory will be entirely replaced by a wide choice of films.

The engineer can make an immense contribution during the next generation to the world food problem by studying how to control the weather and particularly in producing rainfall in arid regions. He is unlikely to be able to do this by brute force as in H. G. Wells's 'wind machines', but he will be able to do it by harnessing the natural forces of solar energy and using the water of the oceans combined with waterproof plastics and earth-moving machinery; to put it in another way, he will learn how to make use of geographical conditions for his own purposes.

### Conclusions

(1) In addition to the two cultures, literacy and numeracy, there is a third: trained skill with the hands.

The happy man is the man who has achieved the highest development possible for him of all three cultures and uses it for real creative work. The necessity of this third culture to every man and woman is frequently underestimated.

(2) The university-trained engineer should acquire all three types of skill—skill in human relations and communication and value judgments; skill in 'physical thinking', that is, using the basic scientific principles in an inventive way; and thirdly, skill in understanding things and materials through his hands.

(3) The engineer can make a positive contribution to changing the future by inventing those machines which make the best and most fruitful changes in man's life. Particularly he can reduce drudgery and the number of hours of work a week that a man or woman has to contribute as their share to the production of all the necessities of life, so that everyone has plenty of energy and free time to satisfy their creative urge by acquiring and using all three kinds of skill.

(4) The universities have the responsibility of teaching a greatly increased flow of engineers not only to be inventive but also how to satisfy their natural altruism by applying their inventiveness in a way genuinely beneficial to mankind.

(5) If British industry is to compete successfully with other technologically advanced countries our universities must train as big a proportion of our brightest youth to be engineers as the universities and Technische Hochschule of the Continent and the United States.

(6) The extra leisure which machines can give mankind will only be profitable if the universities start now to plan for increased leisure by giving positive encouragement to the creative arts and hobbies as non-specialist, non-career subjects for enjoyment.

## MUSKEG IN ARCTIC NORTH AMERICA

By PROF. NORMAN W. RADFORTH

Department of Biology, and Chairman, Organic and Associated Terrain Research Unit,  
Hamilton College, McMaster University, Ontario

WITH growing interest on the subject of genesis and organization in organic deposits, I thought there could be advantage in examining the relationship between freshly exposed inorganic land surface and the onset of the deposition process of organic overburden. There are no records of any search having been made for muskeg (organic terrain, or peatland, as it is also known) in the Arctic Archipelago of North America where remnants of the ice-cap have long been known to exist. Accordingly, I visited the northernmost island in the Archipelago (Ellesmere) to see if in fact organic terrain did exist that far north and in proximity to retreating faces of the ice-cap. It was hoped that if muskeg did exist, its mode of origin might be used to explain some of the phenomena which characterize well-established organic terrain so prevalent at lower latitudes in North America and elsewhere in the world.

Two surveys were made, the first in 1962 during mid-summer. In this expedition, peat, with living cover, was discovered on the flatlands at the head of Goose Fjord and at Okse Bay. It was also found much more than 100 ft. up the slopes of certain branches of Goose Fjord approximately 100 yards from the face of the permanent ice-cap.

By direct inspection from a small airplane flying at low altitude, patches of organic terrain could be discerned. These were interrupted by large expanses of inorganic terrain which from time to time showed evidence of plant life but not of peat. In both the organic and

inorganic terrain, geomorphic pattern on the local basis was marked.

The second expedition, in the summer of 1963, was partly to examine the constitution of the peat and the causes of geomorphic pattern as it was associated with organic terrain. Another objective in returning was to see whether organic terrain existed as far north as land was known to extend in the Archipelago.

During this journey shallow peatland was discovered less than 100 ft. from stranded pack-ice no more than 1 ft. above sea-level on the northern coast approximately three miles from Alert. Peat deposits covered with actively growing vegetation were also found several hundred feet up the slopes of Crystal Mountain near Alert at the northern extremity of the U.S. Mountain Range. Organic terrain occurred sporadically elsewhere in the vicinity of Alert and sometimes partly covered by snow-drifts that would obviously outlast the summer.

In an aerial traverse made in low-altitude flight between Alert and Camp Hazen on the north-westerly shore of Lake Hazen, sporadic occurrence of organic terrain was again noted. In many cases, it was recognized by an interpretive method close to terminal faces of the ice-cap. It was estimated that shallow peatland occurred less than 100 ft. from the toe of Eugene Glacier. The presence of pattern ground was also detected during this aerial traverse, and pattern was more varied than it was in cases typifying conditions at Goose Fjord, Okse Bay, and elsewhere in the southern portion of Ellesmere Island.

Fig. 1

Examples of organic terrain showing two different patterned conditions are presented in Figs. 1 and 2 on photographs taken in the vicinity of Camp Hazen in the foothills of the U.S. Mountain Range.

From initial examinations made of the peat samples removed from beneath the living cover of the organic terrain, it may now be claimed that pollen, cuticle, and certain plant tissues have been preserved well enough to facilitate botanical identification. The peat, sometimes 1 ft. deep, but more often shallower, differed somewhat as to structural type, but, given the type, constancy as to structure was marked. This phenomenon has already been reported in earlier work on peat types at lower latitudes on the continental mainland<sup>1</sup>.

On Ellesmere Island it was easy to examine distribution of loci of peat initiation through comparative examination on the land where colonization and initiation of peat were contemporaneous. It became clear that usually, once peat type was established, constancy as to type could be expected. Peat in different orders of depth of a single structure type was usually covered by living plants which symbolized and (by reference to habit or 'life-form') characterized peat type beneath them.

From these observations it could be deduced that the colonizers of the new land displayed persistence of biological individuality in the process of becoming established and of spreading to provide total cover for the terrain. Certainly so far as peatland is concerned it could be reasoned that in the process of establishment, succession should be viewed in terms of recurring generations of the same life-form and change from one life-form to another a marked exception. This would account for the fact that significantly large areas of organic terrain do in fact arise independently and retain their cover type even though such constitutionally different areas become contiguous.

When contiguity is in evidence and the cover types of the component areas differ, lines of demarcation appear in what has become continuous or 'unconfined' muskeg. This feature obviously makes its contribution to designation of patterned ground.

Several types of covering vegetation occurred on the peat. A method for differentiating cover types has been expressed elsewhere by me for muskeg at relatively southern latitudes<sup>1</sup>. Types of cover designated by the symbols (cover formulae) *FI*, *EI*, *EFI* and *I* were common on Ellesmere Island.

The environmental inducers of peat formation and the controls which maintain constancy and independence of plant type are still under investigation. Near the ice cap, where peat is originating and the water factor in the environment is such that there is movement of water, the cover type is *EFI*. If the water is motionless the type is *FI*. If there is no free water exposed at the site, the cover type is most commonly *EI*. On slopes and at high altitude the common cover type was *I*.

It would appear therefore that the water factor, on the basis of qualitative examination, is most significant both in the process of initiating peat type and in maintenance of type. Peat appears to form on all types of mineral foundation ranging from silty clay through silt, sand, fine and coarse gravel. Because each of these soils in special ways is often associated with characteristic and perhaps peculiar geomorphic disturbance to the type of mineral matter, the disposition of water varies accordingly. Peat type would appear to follow this dispositional factor and through it one can with reasonable safety predict association of peat type with mineral soil type, but always the latter seems secondary as an agent in controlling peat type.

If the observations and explanations noted are evaluated, one might predict that what the writer has referred to elsewhere as air-form pattern<sup>3</sup> might appear in air photographs of the Ellesmere terrain. The facts confirm that polygoid and vermiculoid air-form patterns are exemplified in Ellesmere organic terrain.

It has also been confirmed near Lake Hazen that both regular and irregular peat plateaux<sup>1</sup> exist. When these topographic features occur at lower latitudes they contribute as main features to the high-altitude air-form pattern designated as marbloid<sup>2</sup>. Local recession and overgrowth in dynamics of peat formation occur where mar-

Fig. 2

loid is characterized. Thus it may be concluded not only that the marbloid condition is generated with other air-form patterns at high latitudes and where colonization of new land surface occurs but also that a factor inherent in the organic material itself takes part in controlling rate and amount of deposition of peat.

Sometimes microtopographic features known to exist in mineral terrain also occur in organic terrain. Polygons<sup>4</sup> are a case in point. On relatively new land surface it is possible to show that given boundaries of polygons may be initiated in mineral terrain and be projected into the adjacent organic overburden (Fig. 1; note that the cleft in the mineral terrain of the hillside on the far slope is projected into the organic terrain covering the valley floor).

The way in which other pattern components arise can also be explained better where colonization of 'new' land surface anticipates muskeg formation. The 'bars' in vermiculoid may be shown to start from sorting processes arising in aggregates of mineral terrain. The sorting, promoted by combined action of ice and water activity, is followed by initiation of peat which maintains and accentuates the identity of the bars. On the other hand, it can be shown now how 'ridging' occurs within organic terrain from coalescing mounds to give 'bars' independent of influence of underlying mineral terrain.

Broader theoretical conclusions are also afforded through the Ellesmere Island investigations. Temperature as a climatic factor controlling peat and cover type is not

necessarily limiting: the constitution symbolized by FI (ref. 1) is now known to occur in a range of latitude at least 4,000 miles wide in North America. This phenomenon, when associated with independence of origin of peat types and predominance of constancy rather than successional change, goes counter to the concept of climax. Finally, lack of a lichenaceous cover type on newly forming muskeg—a condition noted on Ellesmere Island—does not necessarily signify that presence of this type in the south may not be used as an indicator of permafrost (cf. ref. 5, where I claim that lichenaceous cover signified presence of permafrost). When the peat on Ellesmere becomes deep enough, free water at the peat surface will be lacking. This condition will mark the initiation of the lichenaceous cover and EI cover type<sup>1</sup> will become HE. This is indirectly substantiated by observation in aerial traverses to the south from Ellesmere Island. 'H' (cover symbol for lichenaceous habit) comes into view significantly before continental mainland is reached.

This work was supported by the National Research Council of Canada and the Defence Research Board, the former in connexion with ground studies of muskeg, the latter in connexion with aerial studies.

## EXPERIMENTAL LUNG CANCER: AN ATTEMPT TO PRODUCE EPITHELIAL CHANGES IN THE RESPIRATORY TRACT OF STRAIN A/J MICE USING 3-METHYLCHOLANTHRENE

By DR. MATTHEW B. DIVERTIE

Section of Medicine

AND

DR. JACK L. TITUS and DR. ROY G. SHORTER

Section of Experimental and Anatomic Pathology

Mayo Clinic and Mayo Foundation, Rochester, Minnesota

THE polycyclic hydrocarbons have long been known to be carcinogenic and, because of their frequent presence as air pollutants, have continued to occupy the attention of investigators in the field of lung cancer. The local application of these chemicals to the respiratory passages of laboratory animals has had variable success in experimental cancer production, and the tumours produced have only rarely resembled those found in human beings. When carcinomas similar to those in human beings have resulted, the methods by which these hydrocarbons were introduced differed frequently from the normal inhalation of these substances in environmental air. The production of squamous metaplasia and epidermoid carcinomas in regions of pulmonary infarction in the lungs of rats with the polycyclic hydrocarbon 3-methylcholanthrene<sup>1</sup> is of considerable interest, since tumours of this cell type occur frequently among human lung cancers, and small pulmonary infarcts may be found incidentally during thoracic surgical procedures or at necropsy. It was the purpose of the work recorded here to determine whether this hydrocarbon might produce similar changes in the lungs of mice genetically predisposed to pulmonary adenomas but in which the factor of local damage was not present.

Forty-eight 6-week-old strain A/J mice and an equal number of control mice of strain C57BL/6J of the same age were injected in sexual pairs with either 0.4 ml. of lard or a mixture of 0.4 ml. of lard and 1.6 mg of 3-

methylcholanthrene. Twelve male and 12 female strain A/J mice and a like number of C57BL/6J mice were given the lard and methylcholanthrene mixture, and 12 males and 12 females of each strain were given the lard alone. Prior to injection, the lard was maintained at mouse body temperature (38° C)<sup>2</sup>, and the needles and syringes were heated before use in order to keep the vehicle liquid. All injections were made subcutaneously into the interscapular region. The animals were housed in standard mouse cages at an environmental temperature of 72°–74° F, fed with Staley's Rockland R4 pellets, and allowed free access to water.

Afterwards, animals were killed with ether anaesthesia at 2-week intervals from 2 to 12 weeks inclusive after the initial injections, at the same hour of the day that the injections had been given. At the time of death, the lungs, bronchi, and trachea were removed in one piece and inflated. They were placed in 10 per cent buffered formalin solution and later were embedded in paraffin wax. Serial horizontal sections were cut at intervals of 8μ through both lungs and major airways to represent a cross-section of the entire pulmonary parenchyma, trachea, bronchi, heart, and mediastinal contents. The sections were stained with haematoxylin and eosin and examined by light microscopy.

Sixteen animals were killed on each occasion, eight from each strain. These numbers were further subdivided in sexual pairs in the control and study groups.

No tumours were encountered in any of the lungs in the first 4 weeks after injection. Between the sixth and twelfth weeks, 32 animals of each strain were killed, and 25 strain *A/J* mice (11 males and 14 females) were found to have lung tumours. Twenty-three had been given 3-methylcholanthrene and lard, and two had been given the lard alone. No tumours were found in the control group of *C57BL/6J* mice. Histologically, all the tumours were adenomas, apparently of alveolar origin. Many were multiple, and all were situated in the lung parenchyma itself; squamous metaplasia or squamous cell carcinomas were not found.

The development of a tumour results from an unknown alteration in the hereditary characteristics of the cells from which it arises. Present knowledge suggests that the carcinogenic process responsible for malignant tumours occurs in two stages<sup>3</sup>. The first is the relatively rapid and irreversible mechanism of initiation during which cellular mutation takes place without recognizable histological change. This is followed by the more gradual and potentially reversible stage of promotion by which the process of malignancy becomes obvious. All known tumour promoters cause epithelial hyperplasia; but although this permits recognition of the temporal sequence of events, this hyperplasia may not be of major importance in tumour production—but only an accompaniment of it.

Although *C57BL/6J* mice have a negligible incidence of spontaneous or induced pulmonary tumours, more than 75 per cent of inbred strain *A/J* mice have been shown to have spontaneous pulmonary adenomas of alveolar origin by the age of 18 months<sup>4,5</sup>. Metastasis is occasionally found in distant organs, and the primary tumours are often multicentric<sup>6</sup>. The subcutaneous injection of polycyclic hydrocarbons has resulted in a shortening of the development time of these adenomas, which then appear in a majority of the susceptible strain within 12 weeks<sup>7</sup>. The numbers of strain *A/J* mice (48 per cent) that developed typical adenomas within 12 weeks of the subcutaneous injections of methylcholanthrene in this experiment is in keeping with these observations. In these circumstances, it seems reasonable to assume that adequate absorption of the chemical occurred in this group and that the lungs of these mice, already genetically conditioned to produce these tumours, were exposed to its action. The intravenous route of administration was avoided in order that pulmonary infarction would not occur. The only known initiating factor in the production

of these tumours was the genetic predisposition of this strain of mice to tumour development, which involved the lung parenchyma diffusely. The tumours themselves do not bear any resemblance to squamous cell epitheliomas or other human bronchogenic carcinomas.

In contrast, Stanton and Blackwell<sup>1</sup> were able to produce squamous metaplasia and squamous cell carcinomas in the lungs of rats after methylcholanthrene was given intravenously in a suitable medium. They observed that malignant lesions did not occur in the absence of pulmonary infarction. The focal damage produced was the most significant factor identified apart from the action of the hydrocarbon itself. The results of the work recorded here substantiate the efficacy of methylcholanthrene in accelerating the development of hereditary lung tumours in strain *A/J* mice. They also show that it failed to produce squamous metaplasia or squamous cell carcinomas in the lungs of these mice, even though genetic predisposition to spontaneous pulmonary adenomas existed. While allowance must be made for difference in species, it seems significant that the same carcinogen produced such changes in regions of focal damage in the lungs of rats without a known tendency to produce lung tumours. This gives indirect support to the suggestion that induced injury of this type to a non-conditioned lung is important in the production of these experimental tumours<sup>1</sup> and appears to be more significant in producing premalignant epithelial change than diffuse congenital susceptibility to tumour formation, within the conditions of the investigation. The influence of genetic factors on the cell type of a subsequent tumour remains unknown. In this work, shortening of the time of development of heritable pulmonary adenomas was not associated with any detectable alteration in the behaviour or morphological appearance of the tumours themselves, which was similar in all respects to those previously described by others<sup>5,6</sup>.

This work was supported in part by research grant CA-06872 from the U.S. National Institutes of Health, Public Health Service.

## OBITUARIES

### Sir George Simpson, K.C.B., F.R.S.

GEORGE CLARKE SIMPSON was born at Derby on September 2, 1878, third of the seven children of Arthur and Alice Simpson. He left school at sixteen and was for two years in his father's business. This he left for Owens College, Manchester, then one of the three colleges of Victoria University. There he sat under Arthur Schuster and Horace Lamb and graduated in 1900 with first-class honours in physics. In 1902 he was awarded an 1851 Exhibition. On Schuster's advice he went first to Göttingen, then a centre of research in atmospheric electricity, and in September 1903 to Karasjok, a village in Lapland, away from the coast, in lat. 69° 17'. He chose this in order to find how the conditions in the absence of daylight in winter and in continuous daylight in summer differed from those revealed in the temperate zone by the relatively new weapons of Ebert, Elster and Geitel, and Benndorf. The results of a year's work were given in a paper in the *Philosophical Transactions of the Royal Society*, 1905. Potential gradient in winter was double, and its diurnal variation treble, the summer values.

Radioactivity was greater than that measured anywhere previously. Both positive and negative ionization at low temperatures of -20° C were less than half their values at 0° C. These and many other results were a rich harvest.

After his return, Simpson worked for a time, without pay, in the Meteorological Office investigating the relation between the Beaufort number, *B*, for wind force and the speed of the wind, *V*, at a height of about 30 ft. above ground in an open situation. The result was, briefly,  $V = 1.87 B^{3/2}$  m.p.h. and led, twenty years later, to the international adoption of *B* for reports of wind.

In 1906 Simpson joined the India Meteorological Office. At Simla, in his spare time, he attacked the problem of the electricity of thunderstorms, a problem which was to exercise his mind for more than thirty years. He designed, and set up, apparatus to record automatically the charge on falling rain and at the same time made experiments to ascertain the charge, if any, on drops of water after splitting up. From the records for the five months, April–September 1908, he found that the charge on rain was predominantly positive, always positive on

rain falling at a rate greater than 0.5 mm/min, contrary to the generally accepted belief that the predominant charge was negative; the laboratory experiments showed that drops of distilled water, broken into spray by a jet of air, became positively charged, the air becoming negatively charged. From these results and the fact that, in thunderstorms, there are vertical currents greater than 8 m/s, that is, enough to carry the largest raindrops upwards until they split, Simpson concluded that a thundercloud must have positive electricity in its central part near its base and negative electricity higher up and away from the centre. This he maintained with firm confidence, in a succession of papers, against the protagonists of the 'influence theory'. Eventually he designed apparatus, carried by free balloons, which recorded the sign of the electric field during the ascent through thunderclouds. Ascents from Kew in 1934-6, and again in 1937-9, showed a positive charge in the upper layers, for which C. T. R. Wilson had contended, a wide distribution of negative in the lower layers with a positive charge near the active centre, as Simpson had pictured it. The upper positive charge and the negative charge beneath it were always at levels where temperature was well below the ice-point. Simpson interpreted this as meaning that the separation of the electricity there was due to collisions of ice crystals.

In 1909 Captain Scott invited Simpson to go as meteorologist with him to the Antarctic. Simpson accepted, came to England to collect the equipment and sailed from London on the *Terra Nova* in June 1910, arriving at McMurdo Sound on January 4, 1911. The ship had nearly foundered when the pumps failed in a very bad storm in December. Observations on the voyage of potential gradient, round the clock, gave for the first time its diurnal variation at sea. At Cape Evans he kept complete meteorological and magnetic records for a year until he was recalled, a year earlier than expected, owing to the illness of Dr. G. T. Walker, his chief in India. In the following seven years, first full of administrative work, then service with the army in Mesopotamia and secondment to the Indian Munitions Board, he wrote a paper demonstrating that coronae seen in the Antarctic could only have been due to liquid-water drops in the atmosphere at temperatures far below the ice-point; and a second paper showing that the spatial distribution of the amplitude and phase of the semi-diurnal variation of atmospheric pressure indicated that it was compounded of two waves, one from east to west and one from equator to pole. In 1920 Simpson was the physicist member of the Egyptian Government Commission appointed to advise on projects for the further regulation of the Nile.

At the end of that work Simpson returned to England to succeed Sir Napier Shaw as director of the Meteorological Office, a post which he held from September 6, 1920, to September 2, 1938. Control of the Office had been transferred to the Air Ministry; and the Meteorological Branches of the Admiralty and Air Ministry, and the British Rainfall Organization, had been officially included in the Office. It fell to Simpson to make the unified organization a good and satisfied scientific service. This he did surprisingly well, in spite of the 'Geddes Axe' and the fact that, like Aphrodite, the Meteorological Office sprang from the sea. The staff was largely drawn from those who had entered meteorology during the War; one of the ablest was most unfortunately lost with the airship *R 101*. By 1926 the Office was running well enough for Simpson to be able to take up again the thunderstorm problem and, after that, the balance between the retained solar radiation and the outward radiation from earth and atmosphere. By taking account of Hettner's confirmation of the 'window' in the infra-red spectrum of water-vapour, indicated in 1898 in the experiments of Rubens and Aschkinass, he was able to make close approximations to the outgoing radiation from the Earth, the troposphere and the stratosphere in different zones of latitude and

thence the horizontal transfer of heat necessary to ensure radiative equilibrium. This led him to the deduction that an increase in solar radiation would cause an increase in cloud and precipitation and possibly have a bearing on the problem of ice ages. He pursued this idea in a number of papers, arriving at the conclusion that an increase of solar radiation would cause first an extension of the polar ice and then a retreat, while the subsequent decrease of the radiation would turn the retreat into an extension followed by a second retreat.

On the outbreak of War in 1939, Simpson offered his services to his successor, Sir Nelson Johnson, who accepted his offer and put him in charge of the four Observatories and the Edinburgh Office, with his headquarters at Kew, where he was able to make further investigations of the electricity carried down by rain. He was president of the Royal Meteorological Society during 1941-42. His increasing deafness in the 1930's made him decline nomination as successor to E. van Everdingen, on the latter's retirement in 1935 from the presidency of the International Meteorological Committee in whose work he had taken and continued to take a very active part.

Simpson was elected Fellow of the Royal Society in 1915 and appointed K.C.B. in 1935. He married Dorothy, daughter of Cecil and Alice Stephen, at Sydney in September 1914. They had three sons and a daughter, all still living. He died on New Year's Day in hospital at Bristol after a short illness. The simple funeral service on January 6, with the first few moving verses of *Wisdom III*, was held at Westbury-on-Trym, where they had lived since they left London in 1961.

E. GOLD

#### Prof. A. F. Barker

PROF. A. F. BARKER died on July 22, 1964, in Portland, Victoria, Australia, at the age of ninety-six. Several obituary notices have already been published, in which tributes were paid to this remarkable man who had devoted the whole of his long life to the textile industry. He was head of the Textile Department at the Bradford Technical College from 1892 until 1914 and professor of textile industries in the University of Leeds from 1914 until his retirement in 1933. At the invitation of the Chinese Government he then took up an appointment as professor of textile industries at the University of Chaio-Tung, Shanghai, but because of the Japanese invasion of China he eventually migrated to Australia, living first in Melbourne and then in Portland, Victoria, where his address was appropriately 'Merino Cottage'.

Prof. Barker was a great enthusiast for textiles. He was very aware of the need for the industry to adopt scientific methods, and to that end he was proud to have introduced into the Department of Textile Industries in Leeds such men as the late Prof. W. T. Astbury and Prof. J. B. Speakman. He realized also the importance of a professional organization for the textile industry and was a Founder Member of the Textile Institute, which now has a membership approaching 8,000. In addition, he was active in promoting more local societies such as the Bradford Textile Society.

His death affords an opportunity to place on record the vast changes which occurred in the wool textile industry during his working life. In his early days textiles was essentially a craft industry, dominated by highly skilled men whose jealously guarded methods of processing had little to do with rational thought. Nevertheless, the products were of surprisingly good quality and British wool textiles were highly regarded throughout the world. Man-made fibres were unknown and the processing machinery had changed little over the years. Although the achievements of science were well appreciated in some industries, the potentialities of science in the wool textile industry were almost completely unrecognized. Within Prof. Barker's life-time, however, this situation changed completely. He was not himself a professional

scientist, but he recognized that the future even of the wool industry would be determined by the extent to which it used the findings of the increasing number of chemists, physicists, engineers and biologists being trained in the universities. Fortunately the wool industry has taken full advantage of the opportunity and is now based on sophisticated applied science and engineering.

Whereas fifty years ago the structure of wool was almost unknown, now, as a result largely of the work pioneered by Astbury and Speakman in Leeds and actively pursued by other groups of investigators not only in Britain but also in France, Sweden, Germany, the United States, Australia and South Africa, it is sufficiently well established to form the basis on which new and commercially significant processes have been developed and which increase the usefulness of wool. In the engineering field, processing has been rationalized and new machines such as the Raper 'Auto-leveller', the Ambler 'Superdraft' system of spinning, and the Sulzer weaving machine have been produced, while advances in biological research and animal husbandry have greatly increased the amount of wool available. The industry is progressive, modern and exciting. In Britain it is well served by an active Research Association and there are ample facilities for training personnel in technical colleges and in universities. The modern industry is based on sound science and ingenious invention and its problems are challenging ones. It offers, and will continue to offer, intellectually rewarding careers for young people with a wide variety of talents, for few industries require the services not only of scientists, technologists, engineers and economists but also of men and women with a true flair for style and design.

In a wider context a note such as this would not be complete without some mention of the fundamental scientific consequences of the researches on the structure of wool, for out of these have emerged important aspects of the new science of molecular biology. Moreover, the complexity of wool—an insoluble protein—necessitated the development of new techniques to obtain information about the sequence and proportions of the constituent amino-acids. One of these procedures, that of partition chromatography, was developed by A. J. P. Martin and R. L. M. Syngé working in the laboratories of the Wool Industries Research Association, and for this work they were awarded the 1952 Nobel Prize in Chemistry.

Until just before his death Prof. Barker retained an active interest in textile education and developments, and he must have been gratified to observe the ever-increasing significance of science in the industry which meant so much to him.

C. S. WHEWELL

#### Dr. Peter Pringsheim

AFTER a long life-time devoted to the subject of luminescence, Dr. Peter Pringsheim died on November 20, 1963.

He was born on March 19, 1881, son of Prof. Alfred Pringsheim, mathematician, of Munich, and took his doctorate there under Röntgen in 1906 with a dissertation on "The Minimum Potential for Spark Discharge". Periods of work at Göttingen, Cambridge (under J. J. Thomson) and Berlin followed, and the summer of 1914 found him in Australia with the meeting of the British Association for the Advancement of Science. Here he was interned for the period of the First World War, after which he returned to Berlin, married his Belgian wife in 1923, and was appointed full professor of the university in 1930. Three years later the Hitler régime caused him to leave Germany for a chair in the University of Brussels, which he retained until 1949. However, he was caught up with again in 1940 by the invasion of Belgium in the Second World War, and sent to internment in the south of France, but obtained liberation the following year on an American visa to carry out research at the University of California, Berkeley. His knowledge of the lumi-

nescence of uranyl compounds was doubtless the reason for his transfer to the University of Chicago, during 1942-44, and again as visiting professor during 1946-47, after an interval as director of research, Ray Control Co., Pasadena.

During 1947-55 he occupied the post of senior scientist, Argonne National Laboratory, Chicago, retiring at the age of seventy-five to Antwerp.

Pringsheim was an active research worker and an assiduous amasser of information from all sources on his chosen subject. Eighty publications, in fourteen journals, describe his investigations; the subjects include the polarization of fluorescence from vapours and dye solutions; general observations on fluorescence and photochemical changes in solutions of hydrocarbons, of dyes and of uranyl compounds and metal complexes; and luminescence and colour centres in irradiated crystals. The introductory chapter in his book *Luminescence* (1943) exhibits his interest in the ancient history of the subject together with his precise yet light touch in description.

His first book, *Fluoreszenz und Phosphoreszenz im Lichte der neueren Atom-theorie* (Springer, Berlin, 1921; third edition, 1928), was written during his time of internment in Australia, and remained for many years the only authoritative book on the subject. Important contributions were made also in Volumes 19, 21 and 23 of the *Handbuch der Physik* (Springer, Berlin). In 1943 he produced, in collaboration with Marcel Vogel, *Luminescence of Liquids and Solids* (Interscience), and finally, in 1949, his massive work, *Fluorescence and Phosphorescence* (Interscience), dedicated to James Franck. This book, containing more than 1,900 references to the literature, has been of immense value to recent workers in this subject of increasing topical interest, not only because of its completeness and reliability, but also because of the clear and critical exposition of the facts in a manner so characteristic of the author.

Pringsheim, during his life-time, was acquainted or associated with all the leading figures carrying out work on luminescence, such as James Franck, Pohl, Hertz, Jablonski, Terenin and Vavilov, and followed its transformation from vague pre-quantum ideas to present-day concepts, constantly both forward and backward looking. Without him the subject would have lacked a great teacher and adviser.

In 1937 he was elected Foreign Member of the Polish Academy. His wife survives him. E. J. BOWEN

#### Dr. A. A. Benedetti-Pichler

DR. ANTON ALEXANDER BENEDETTI-PICHLER, who died suddenly on December 10, 1964, was a pioneer in the establishment of microchemistry in the United States.

Born in Vienna, Austria, in 1894, Dr. Pichler received degrees at the Technische Hochschule in Graz, where he worked for many years with the pioneer in microchemistry, Hofrat Friedrich Emich. It was during his years with Dr. Emich that Pichler learned from him the importance of extreme attention to minute details, which showed up through all his life in his contributions to the field of microchemistry and to general analytical techniques. "During the early years," he once said, "Emich was a very exacting chief, and I did not have an easy time. Later, he relaxed when he found that I really tried to do my best."

After obtaining the *venia legendi* in analytical chemistry, Dr. Pichler decided to take up permanent residence in the United States in 1929, in order to introduce the inorganic microchemical working procedures of Dr. Emich and his co-workers there, and to raise the standards of the analytical chemist.

Mainly through the consistent efforts of Dr. Pichler in the 1930's there have been laid the solid foundations of the Microchemistry Section in the American Chemical

Society, now the Division of Analytical Chemistry. He was also instrumental in the establishment of the Metropolitan Microchemical Society, now the American Microchemical Society. Both organizations guarantee future improvement in the status of analytical chemists and permit a more scientific approach to analytical problems.

With his co-workers, Dr. Pichler laid the foundations of the techniques in handling ultra-micro amounts of samples by strictly logical and mathematical treatment of the principles established for the milligram and microgram ranges by both Emich and Pregl. Based on this fundamental work, it was possible to develop, quickly and efficiently, the chemistry of the transuranium elements which led to the Manhattan Project during the Second World War, and the atomic bomb.

British analytical chemists are familiar with Pichler's work, having listened to his brilliant plenary lecture at the Birmingham Analytical Symposium in 1958. International societies heaped numerous honours on Dr. Pichler; for example, he received the 1932 Fritz Pregl prize in microchemistry from the Academy of Sciences of Vienna; the Emich Plaque of the Austrian Society for Microchemistry in 1955; the Honor Insignia of Arts and Sciences (First Class) from the President of Austria in 1962; and the Anachem Award of the Association of Analytical Chemists in 1963.

His love for beauty in Nature took him on extensive trips to the western parts of the United States on several occasions, and influenced him not only to become a member of the National Parks Association, but also to stay in the United States.

He also decided to develop several acres of farmland near Camden, South Carolina, primarily for his wife, the daughter of an Austrian forester. While there, he became interested in conservation. With the help of the local representative of the Department of Agriculture, he was striving to restore the farm's fertility at the time of his death.

His desire for accuracy can be illustrated by his research on establishing the origin of paintings. He found it necessary to study methods of painting in oil himself so he could interpret correctly his findings of the authorship of paintings and the period of applications.

His dry sense of humour may have caused him to be misunderstood among the people who met him, but students and associates admired him for his brilliant, scholarly mind. They loved his lectures in which he logically developed his points, and the splendid demonstrations, with the simplest equipment proving the essential points of his dissertation.

His final inheritance to the world he left behind was the book *Identification of Materials, via Physical Properties, Chemical Tests and Microscopy*. It represents a summary and splendid combination of experiences during his lifetime in scientific microchemical approaches, in teaching analytical chemistry and in consulting work to large industrial concerns.

Dr. A. A. Benedetti-Pichler must be considered as one of the pioneers in microchemistry, alongside Emich, Feigl and Pregl, especially for introducing it in the United States. To his students and associates he will be remembered as the precise, modest, true scholar and beloved friend.

H. K. AND W. R. ALBER

## NEWS and VIEWS

### Organic Chemistry in the University of Leicester :

Prof. C. W. Rees

DR. C. W. REES, reader in organic chemistry at King's College London, has been appointed professor of organic chemistry in the University of Leicester. Dr. Rees was a student at University College, Southampton, from 1947 until 1953. After working under Dr. (now Professor) N. B. Chapman, he took up an appointment under Prof. A. Albert in the Department of Medical Chemistry of the Australian National University, which was then operating in London. He joined Birkbeck College as an assistant lecturer in chemistry in 1955 and became lecturer in 1956. In the following year he transferred to King's College, London, and was later promoted to a readership. Dr. Rees's research interests have centred largely on the chemistry of heterocyclic compounds with special reference to the mechanisms of their reactions. Certain aspects of his work have been supported by the Medical Research Council and by the British Empire Cancer Campaign. He has numerous publications in the *Journal of the Chemical Society* and in recent years he has been responsible for the section on Organic Reaction Mechanisms in the *Annual Reports on the Progress of Chemistry*.

### The National Institute for Research in Nuclear Science

At the Committee stage of the Science and Technology Bill in the House of Lords on February 23, Lord Bridges again raised the question of the position of the National Institute for Research in Nuclear Science under the Science Research Council. He was concerned that its relations with the Atomic Energy Research Establishment at Harwell might be affected adversely and also that, since from April 1 the laboratories of the National Institute would come under a Nuclear Physics Board, reporting to the Science Research Council which, in turn, reported to the Minister of Education and Science, the

lengthened lines of communication would lead to delay and frustration. He suggested that the Science Research Council should be sufficiently well staffed to be given very wide delegated powers to settle questions of finance and administration, including possibly authority to appoint staff. Lord Bridges was supported by Lord Sheffield and the Earl of Bessborough, and the Parliamentary Secretary to the Ministry of Technology, Lord Snow, readily gave Lord Bridges the specific assurance for which he asked, that absorption of the National Institute for Research in Nuclear Science under the Science Research Council would not be used to impose a more rigid bureaucratic system of control in finance and administration, including the appointment of staff. However, Lord Snow firmly defended the proposed arrangements, and the Minister of State for Education and Science, Lord Bowden, later added that the decision as to whether the Institute and the Atomic Energy Authority should come under the Science Research Council was only taken after very considerable debate. It was decided that the Bill allowed sufficient flexibility, if the proposal proved unworkable, to make a change by administrative action without seeking further legislative powers. On finance, Lord Snow explained that within its annual estimated provision, the National Institute had delegated powers up to £25,000 from capital expenditure and the Authority up to £100,000; above this, authorization by the Secretary of State and the Treasury was required. The Finance Member of the Authority was a member of the Board of the Institute. The Department for Scientific and Industrial Research had delegated powers up to £50,000 for capital schemes and the Government was considering the appropriate level of financial delegation for the Science Research Council. The capital expenditure of the Institute in 1963-64 was about £1.6 million, of which £1 million was on schemes of more than £100,000 and £250,000 on schemes between £50,000 and £100,000.

### Britain's Energy Budget

IN view of present controversy over the output of the coal industry, Mr. R. Bailey's article, "The Energy Perspective", in the *Westminster Bank Review* for February 1965, is of special interest. Mr. Bailey discusses the relative contributions of coal and oil to Britain's energy budget, accepting the view that the needs for energy of the non-Communist world by 1985 would be more than doubled to reach the equivalent of 8,000–9,000 million tons of coal, of which 49 per cent might be provided by oil and 18 per cent by natural gas, compared with 45 per cent and 15 per cent, respectively, to-day. Given a 4 per cent rate of growth for the economy, the total consumption of energy in the United Kingdom would rise from the 1962 level of 191 million tons of coal, 78.5 million tons of oil and natural gas, and 3.5 million tons of nuclear and hydroelectric power (or 273 million tons of coal equivalent in all) to totals of more than 300 million tons in 1966 and about 450 million tons of coal equivalent in 1980. Since it appears unlikely on its present showing that nuclear energy will make a significant addition to energy supplies at an economic price in the next 20 years, the bulk of the increase must come from the coal and oil industries. Under its present financial arrangements, the National Coal Board can break even on sales of 200 million tons a year, and marginal tonnage above this is produced very cheaply; hence the problem still remains as to where else a further 100 million tons of fuel can be obtained at £2 a ton. In searching for a policy to reconcile long-term and short-term considerations, Mr. Bailey points out that the questions remain to be answered whether the coal industry should be encouraged to expand its output to a level nearer its primary capacity and maintain it at that level as an insurance against future needs for energy. If this were accepted, how would oil, nuclear energy and natural gas be co-ordinated within this policy, and what part would the secondary fuel producers—gas and electricity—be expected to play, particularly in their selection of primary fuels? Mr. Bailey emphasizes that there are no immediate or short answers to these questions, and that, since Britain imports a quarter of her energy requirements, high priority must be given to maintaining economic production of her major indigenous fuel—coal. The secondary fuel industries of gas and electricity must not follow policies that endanger long-term supplies of the primary fuels.

### British Overseas Research

THE *Review of Colonial Research, 1940–1960*, is edited by Sir Charles Jeffries for the Department of Technical Co-operation, and Lord Hailey contributes a foreword (Pp. 238. London: H.M.S.O., 1964. 21s.). It covers the developments and achievements in colonial research under the Colonial Research Committee and, later, the Colonial Research Council until the functions of the latter Council were in 1959 transferred to the new Overseas Research Council, dissolved last year. There is also a brief review of earlier developments before the first Colonial Development and Welfare Act of 1940. The Survey is in two parts: a general record occupying about a quarter of the book, and a longer section in which various specialists provide more detailed summaries of progress in ten different broad fields—social science, economics, building and roads; health and medicine; agriculture; animal health; forestry; fisheries; plant and animal products; pesticides; locust research and control; and trypanosomiasis. The general record presents an impressive account, which deserves to be widely read, of a contribution to the welfare and development of the emerging countries, of which Britain can rightly be proud, and the details of which, as Lord Hailey observes, can be studied with advantage by those agencies whose mission it is to-day to improve the standards of life in the many underdeveloped countries.

That applies particularly to the new Ministry of Overseas Development, for the picture presented in this Survey does not indicate the extent to which the results of this expenditure of more than £24 million from 1940 onwards have been endangered by what has taken place since many of the territories achieved independence. It is not merely that interterritorial organizations have been endangered by lack of financial support; the failure of Britain to support the Overseas Research Council and its subsequent dissolution have also contributed, and while the general record and the specialist accounts indicate the opportunities and often illustrate the conditions required for success, they do not specifically refer to the recent shortcomings and failures which lie largely outside the period covered. Essentially, the Survey as a whole summarizes, and presents in most readable form, information already published in the reports of the Colonial Research Council and the specialized advisory bodies which reported with it in *Colonial Research*. There is still needed a survey of the trends and developments since 1959 which the Overseas Research Council did not, or was not allowed to, provide. For all that omission, which the Ministry of Overseas Development might well be wise to rectify in some way later, the book should appeal both to the general reader and to the specialist. It could well stimulate not only a more general appreciation of what Britain has already done in this field but also an understanding and appreciation of the value of her overseas research effort which should ensure that support is forthcoming in future on the scale and in the ways required to make that effort increasingly effective.

### Tropical Pastures Research

THE establishment of an International Tropical Grassland Commission is recommended in a resolution passed by the ninth International Grasslands Congress, held in São Paulo, Brazil, during January 7–21, 1965. In sponsoring the resolution, Prof. G. S. Puri (Kwame Nkrumah University of Science and Technology, Kumasi, Ghana) directed attention to the potential food and fodder production of the tropical grasslands. Their origin, and present status, result from shifting cultivation and fire. Although this type of land use is not ideal, it does represent the simplest means of releasing into the soil-plant system the nutrients that are locked up in plant material. Prof. Puri suggested that tropical pasture research should aim at breeding some drought-resistant perennial grasses and legumes to give material of a high leaf/stem ratio during the dry season. Physiological investigations should be directed towards prolonging the production of leafy material, and delaying flowering, in grasses and legumes, and towards reducing the rest period and activating the quick growth of leafy tissues. He pointed out that this work would involve research of a fundamental nature, to which plant physiologists in temperate parts of the world might be expected to contribute. Prof. Puri went on to advocate research into the utilization in husbanding of the tree pasturage, or woodland savannah, which covers so large an area in the tropics. He further suggested that since a satisfactory herbaceous perennial legume for tropical grasslands is not available, use should be made of some of the leguminous trees and shrubs. Tropical grasslands may be classified as 'reversible' or 'irreversible'. The former category comprises land in which trees and/or shrubs are invariably present, and which must therefore be managed on farm-forestry principles. 'Irreversible' grassland usually bears no trees, owing to shallow or waterlogged soil or other causes. They can and should be mechanized, especially as their management as natural grasslands is uneconomic. These types of grassland overlap the savannah types, and Prof. Puri urged that the savannah research section of the Food and Agriculture Organization should undertake the furtherance of this research and the establishment and maintenance of the Commission.

### Agricultural Research in Northern Nigeria

THE Institute for Agricultural Research now covers the work of the Regional Research Station of the Ministry of Agriculture of Northern Nigeria, at Samaru, together with its sub-stations at Shika, Mokwa and Kano. From October 4, 1962, the Stations became the Institute for Agricultural Research, Ahmadu Bello University, and Prof. H. S. Darling was appointed as its director. The first annual report for the year ending March 31, 1963, is now available (Pp. x + 67. Zaria, N. Nigeria: Institute for Agricultural Research and Special Services, Ahmadu Bello University, 1964. 10s.). Soil fertility and the improvement of crop yields are in the forefront of the Institute's programme, which covers crops important to the area, such as groundnuts and sorghum. Some success has been achieved in the yield of oilseed crops such as sesame, soya bean, groundnuts, sunflower and castor. Work in Bulgaria and Russia was not overlooked, and varieties of sunflower from these countries yielded seed of higher oil content than the older standard varieties. A considerable effort was devoted to the groundnut aflatoxin problem. This included experimentation with methods of drying and a study of the factors affecting contamination of the crop by *Aspergillus flavus*. It was concluded generally that seed from broken or termite-damaged pods was the main factor in contributing highly toxic groundnuts to the crop. Work on *Pennisetum* millets involved the trial of several varieties and the effect of spacing on yield and plant disease. The breeding selection and testing programme of the Cotton Breeding Section follows well-established lines. The maximum yield plot gave a yield in excess of 2,000 lb. per acre for the fifth successive year. The report is a record of excellent progress and a testimony to the good work done by the staff of the Institute.

### Applied Mathematics at the Weizmann Institute of Science, Israel

THE autumn issue of *Rehovoth* (3, No. 3; 1964), a periodical published by the Weizmann Institute of Science and Yad Chaim Weizman, Rehovoth, Israel, is a special number devoted primarily to applied mathematics, particularly to some of the work now being carried out in the Applied Mathematics Department of the Institute under the direction of Prof. Chaim I. Pekeris, who founded the Department in 1948. He contributes a stimulating article entitled "A Brief History of the Department of Applied Mathematics". This is, however, far from being a parochial account of the subject from one centre of learning; it is a fascinating, if brief, discourse of a major revolution in science: the drifting apart, after World War I, of pure mathematics, physics and applied mathematics. Fifty years ago, no distinction was made between an applied mathematician and a physicist; as examples are cited the work of Lord Rayleigh (1842-1919), a leading authority on applied mathematics, a Nobel prize-winner in physics (1904), and at the forefront of physical research all his life; also that "esoteric mathematician" David Hilbert (1862-1943), "... who was not only well versed in physics, but himself contributed to the theory of relativity and to the kinetic theory of gases"; again, Henri Poincaré (1854-1912), ast of the giant "natural philosophers", whose profound contributions to pure mathematics, physics and astronomy are well known in the histories of these disciplines. Among many original and shrewd observations made by Prof. Pekeris in this article are: "Today, pure mathematicians receive little training in physics. In some universities one can get a Ph.D. in mathematics without ever having heard of the Second Law of Thermodynamics". He goes on to say that "The chosen audience of pure mathematicians is, clearly, made up of other pure mathematicians. Similarly, physicists, preoccupied with the atomic nucleus, concern themselves with little else". Remarking that

"... there is no peace in the foreseeable future for applied mathematicians", he lists some of the major problems confronting them "... when they can sit in their offices and, with the aid of electronic computers", proceed to their solution. The schedule includes forecasting weather by numerical analysis; prediction of the tides at every point of the world oceans on the basis of tidal theory alone; explanation on the basis of pure theory of every measured atomic and molecular spectral line; determination of the crystal structure of proteins from X-ray photographs; and interpretation of the significance of every wrinkle in a seismogram in terms of the nature of the explosion (nuclear or earthquake), and the internal constitution of the Earth. "Applied Mathematics, at the Weizmann Institute, ranges from the building and designing of computers, to the study of the internal constitution of the Earth and the prediction of ocean tides". This and other articles in this well-produced and illustrated magazine convey impressively an idea of what has been done in the past, and is now being done, in the realm of applied mathematics in its modern conception.

### Administrative Organization of the Soviet Construction Industry

IT may not be generally known that the Department of Scientific and Industrial Research, through its Overseas Liaison Group at Africa House, Kingsway, London, W.C.2, publishes from time to time, for open distribution, reports from United Kingdom Scientific Attachés and Advisers on matters of primary interest to those concerned with the administrative organization of various industries in foreign countries. One such report by T. Garrett, Scientific Attaché, Moscow (U.S.S.R. 32, August 1964), entitled "Administrative Organization of the Soviet Construction Industry", describes the functions and responsibilities of the various organizations concerned, especially those of the U.S.S.R. State Building Committee. This report is most informative and gives an insight into the problems which have hitherto beset, and still do face, the building industry in the Soviet Union. "Great demands are made on the Soviet construction industry and the co-ordination of this complex and widely dispersed organization which employs one-tenth of all Soviet industrial workers is a mammoth task. Following November 1962 ... a number of administrative changes were put into effect, giving more power to the central bodies concerned with construction and relieving the local economic councils (Sovnarkhozy) of their responsibility for building operations. The aim was to reduce the growing number of unfinished and abandoned projects and the resultant waste of capital investment and also to improve co-ordination, bring about a unified technical policy in the construction industry and to make more effective use of available resources." The subject-matter of this report is dealt with under the following headings: the U.S.S.R. Council of Ministers; U.S.S.R. Supreme Economic Council (VSNKh); the State Building Committee (U.S.S.R. Gosstro); Academics of Construction and Architecture; the Scientific and Technical Council; the Main State Construction Inspectorate; Project Organizations; the Republican Councils of Ministers; Republican Gosstro; Republican Ministries of Construction; Main Construction Directorates; Contract Construction Organizations; the All-Union Capital Investments Bank (U.S.S.R. Stroi bank); Party Committees; and the Plan for Capital Construction. The Soviet construction industry, despite this policy of centralization, is thus involved in a somewhat formidable maze of bureaucratic controls which is perhaps understandable having regard to the size and population of the country; fortunately, the report contains two explanatory appendixes, one giving a schematic diagram of the inter-relationships of the various organizations previously noted as now involved in the construction industry; the other, a diagram of the structure of U.S.S.R.

Gosstroi (State Building Committee) with its Collegium (sub-committee for effective guidance and decisions on present-day problems), Functional Directorates (material-technical supply, economics, finance, mechanization, personnel, management and foreign relations) and Branch Directorates (embracing, among other functions, agricultural, chemical and oil industries construction).

### The Mauritius Institute

THE Mauritius Institute was founded in 1880, "for the purpose of promoting the general study and cultivation of various Branches and Departments of Arts, Science, Literature and Philosophy, and for the instruction and recreation of the people". The foundation stone was laid on November 23, 1880, by the Governor, Sir George Bowen, and on December 3, 1884, Sir John Pope Hennessy, then Governor, formally opened the building to the public on the occasion of the Intercolonial Exhibition. The following year the Natural History Museum, known as the Desjardins Museum, which was then managed by the Royal Society of Arts and Sciences of Mauritius (founded 1829), was transferred from the Royal College of Port Louis to the newly erected Mauritius Institute, together with the library of the Royal Society of Arts and Sciences. The Public Library was opened later, in 1902, when the rich collection of books, consisting of some 9,000 volumes, was bequeathed to the Colony by an eminent Mauritian lawyer and politician, Sir Virgile Naz (1825-1901). The Mauritius Institute is now composed of: a public library which includes lending and reference sections; a public museum, composed of natural history, arts and historical sections; the historical museum near Mahebourg; and five learned societies, which use the premises of the Institute for their meetings and for their library. The work of the Institute during 1963 is described in the annual report (Pp. 15. Port Louis: Government Printer, 1963. Rs. 1).

### Computers in Medicine and Biology

THE July 1964 part of the *Annals of the New York Academy of Sciences* (115, Art. 2. Pp. 543-1140) contains a collection of papers on the general topic: "Computers in Medicine and Biology". The contents are divided into seven principal subjects. The first part discusses digital and analogue computers and their relation to biological and medical application, and deals also with the way in which a medical data-processing centre should be organized; the second is mainly concerned with the technology of the computers themselves and describes a number of general and special purpose devices which are particularly appropriate for medical use. The last four sections of the book contain papers on computer applications in specific branches of medicine and biology; neurophysiology, psychiatry and psychophysiology, general biology and cardiology. The collection is a valuable addition to the relatively sparse literature in this field. It is well written and modern in flavour, and everyone interested either in computers or in their application in biology will wish to read it.

### The National Central Library

THE forty-eighth annual report of the Executive Committee of the National Central Library covers the year ended March 31, 1964 (Pp. 24. London: The National Central Library, 1964). Requests for loans reached 107,742 compared with 98,690 in 1962-63 and of these 78.75 per cent were satisfied; some 78 per cent of requests made by the Library abroad on behalf of British libraries were also satisfied. Total loans made by overseas libraries increased from 3,443 to 3,739—British loans abroad increasing from 2,686 to 3,488, while the number of photographic reproductions supplied increased from 603 to 630 for overseas libraries and from 936 to 1,532 for British libraries. West Germany and France were the chief lenders to British libraries, West Germany being

the principal borrower, followed by Hungary, Italy, Denmark, Poland and the U.S.S.R. University libraries supplied 21,088 loans at the request of the National Central Library and 18,049 loans were made by the Library or through its agency to University libraries. Completion of the new building is not now expected before May 19, 1965, and meanwhile the Library has been reorganized on the basis of two divisions, one dealing with inter-lending, the other with the acquisition of books and periodicals by purchase and donation and dealing with all cataloguing and the completion of the Library's master union catalogue. Work has proceeded on the preparation of the British union catalogue of periodicals on a quarterly basis with annual and quinquennial accumulations as from March 1964, and it has been agreed with the Council of the World List of Scientific Periodicals that the two publications should be merged in future. Each annual accumulation will be published in two parts: a general volume containing all periodicals listed in the previous four quarterly parts, and a scientific volume containing periodicals in science and technology. Representations were made in connexion with the Public Libraries and Museums Bill against the proposal to reduce the Government grant to the Library by 50 per cent, and the Act now makes no mention of the State grant to the Library in relation to its total income. The grant for the year ending March 31, 1964, was £95,000 compared with £82,500 for the previous year. A survey of loan requests during the six months January-June 1964 was commenced, and it is hoped that the results will be of service to the Committee on Library and to the Department of Education and Science.

### Micromechanics

SEVERAL microprocessing methods have been developed for use in microelectronics. These include electron beam and more recently laser beam drilling, both of which are thermal processes, but with different effects. An interesting comparison of the two methods of drilling is described by S. Namba and P. H. Kim in the *Japanese Journal of Applied Physics* (3, 536, September 1964). The electron beam machine consists of two chambers, both at a pressure of  $10^{-5}$  mm Hg. The electron beam chamber contains the electron gun, the electrostatic deflector plates and the focusing magnetic lenses. The beam is emitted from a tungsten hairpin filament, and the location of the beam spot on the workpiece and the intensity of the beam can be controlled either by using a television system to monitor the deflexion and intensity of the beam or by moving the workpiece by means of a digital control system. The laser machine consists of a ruby rod 15 cm long, supported inside two helical xenon flash tube enclosed within an aluminium cylinder, and cooled by compressed air. The workpiece is viewed by means of a built-in microscope at times between the laser flashes. The maximum input energy is 12,500 joules, and the laser beam is focused on to the workpiece by a lens. The workpiece carriage can be moved in three mutually perpendicular directions independently. Photographs of etched cross-sections of holes drilled by both beams in various metals, including Ta, Nb, Ni, Mo, Zr and stainless steel, are shown and discussed. Stainless steel was the easiest to process. Quartz, which is transparent to light cannot be drilled by the laser beam. The minimum spot attainable with the electron beam was about  $40\mu$ , in accordance with the theoretical value of several tens of microns, and from 0.3 to 0.6 mm for the laser beam. In thermal processing, drilled holes are generally tapered if the absorbed energy is not so large as to evaporate the material of the whole spot area at once. The holes are larger for the laser beam than for the electron beam, probably because the laser beam is not perfectly parallel and the melt is carried away over a larger area. The laser beam holes are also rarely round-shaped, usually spiky. Though the laser beam processing is simpler and easier

handle than the electron beam processing, because the former requires no evacuation, neither continuous processing nor continuous output of high energy density is possible. The laser beam is, however, better than the electron beam in power efficiency, as estimated by the amount of material evaporated.

### Rubberized Surfacing Materials for Roads

It has long been known that the rheological properties of tar and bitumen are appreciably altered when small proportions of natural rubber are added. Extensive investigations at the Road Research Laboratory into the properties of rubberized binders have been carried out in co-operation with the Natural Rubber Producers' Research Association and the Natural Rubber Bureau, and a series of full-scale road experiments have been initiated during the past ten years at various places in Britain. The results of these experiments up to May 1963 are now available in *Road Research Laboratory Technical Paper No. 71*, by P. D. Thompson (*Full-Scale Road Experiments Using Rubberized Surfacing Materials, 1953-1963*. Pp. iv+24. London: H.M.S.O., 1964. 3s. net). The types of 'black top' surfacing concerned in these experiments are mastic asphalt, rolled asphalt, bitumen macadam, dense tar surfacing, tar surface dressing, and bitumen surface dressing. A summary of the essential results of these road experiments may be stated as follows: (1) Addition of rubber to mastic asphalt prevents or markedly reduces the cracking which occurs when a bituminous surfacing is laid over joints or cracks in a concrete base; (2) addition of 10 per cent of rubber to the binder of rolled asphalt reduces the number and severity of cracks in this surfacing material when laid over joints and cracks in a concrete base; (3) a substantial increase in life is obtained when 4 per cent of powdered rubber is added to the binder of bitumen macadam; (4) "a limited full-scale experiment has suggested that the life of dense tar surfacing may possibly be increased by the addition of rubber powder to the binder"; (5) "in one surface-dressing experiment, a commercially available rubber-tar showed no improvement over normal tar. Interim results of a second experiment suggest that some advantage may be gained by the use of a graft rubber-tar in the tar surface dressing"; (6) "a considerable reduction in the tendency of bitumen surface dressings to 'fat up' in hot weather under heavy traffic has been shown when rubber has been blended with the binder". In so far as the results of these experiments may be indicative at this stage, it would appear that the greatest advantages of rubberized binders are realized when asphaltic bitumen is the major adhesive. The experiment with dense tar surfacing seems inconclusive. In the case of tar surface dressing, a second full-scale experiment has recently been started further to assess the possibilities when graft-rubber is added to the binder.

### Bibliography of Cold Weather Concreting

THE subject of the many and varied technical problems raised in concrete construction during the winter months has for years past been one of major concern in the building and engineering industries; few indeed will readily forget the disastrous conditions occasioned by the severity and duration of the freezing temperatures in Britain in the winter of 1962-63. The subject, however, is one still receiving considerable attention, not only from cement and concrete technologists, but also in its economic and practical significance; this interest is international, at least in temperate climates. The Cement and Concrete Association, London, has recently produced a bibliography covering articles, papers and books dealing with the subject of cold weather concreting practice, the use of ready-mixed concrete under these conditions, and the rearing of aggregates (*Bibliography of Cold Weather Concreting*. Pp. 29. (Ref. Ch.48. 10/64.) Pp. 29.

London: Cement and Concrete Association, 1964. 5s.). This useful document lists nearly 400 references to this subject in international literature, ranging in time from early 1964 back to 1912. This in itself is sufficient evidence of the undiminished importance of the problem and, perhaps, of the still formidable technical obstacles to be overcome before a final and universally acceptable solution is reached (if ever). To those studying cold weather concreting in all its phases, likewise all concerned with the design and construction of buildings, bridges, roads, runways, involving particularly *in situ* concreting under arctic conditions, this bibliography is bound to prove of great value.

### Respiratory Function and Failure

NORMAL respiratory function requires adequate ventilation of alveoli, proper exchange of oxygen and carbon dioxide between air and blood by diffusion, and adequate transport of blood to and from the lungs via the pulmonary circulation. Respiratory failure can occur through dysfunction of any one of these three processes or of two or more in combination. To understand why such failure has occurred and to treat it correctly, measurements of each physiological process may be required. Accurate and easily performed quantitative tests are available and may be used when necessary to supplement information obtained by radiography, bronchoscopy and routine laboratory procedures. Pulmonary function and the tests for respiratory failure are described in the *Central African Journal of Medicine* (10, No. 10; October 1964) by Dr. A. J. P. Graham, who has also advocated their use at the bedside or in the consulting room. A later article will be devoted to describing the clinical picture, and discussing the management of respiratory failure in the acute and chronic stages.

### The Ornamental Sea-toad

A PHOTOGRAPH showing the carapace of the ornamental sea-toad, *Schizophrys dama*, a spider-crab from Broome, north-western Australia, appears in *Australian Natural History* (14, No. 11). Only one other illustration, now difficult to obtain, of this distinctive crab has appeared since the first hand-coloured plate was published in Berlin in 1804 by the German naturalist, Joann Friedrich Herbst, with his original description of the animal. *S. dama* is found inter-tidally and in shallow water from the Albany area of south-western Australia, through western and northern Australia to northern Queensland, and, during life, the carapace is often partly concealed under a cover of sponge and other marine growths. Two thorn-like spines project laterally from each of the elongate rostral horns at the front of the carapace. This feature serves to distinguish *S. dama* from the closely allied red sea-toad, *Schizophrys aspera*, which has only one lateral spine to each rostral horn. *S. aspera* is found in a similar habitat through southern, western and northern Australia and along the entire Queensland coast and Barrier Reef area. It has not yet been recorded from New South Wales or Victoria.

### University News:

#### Bangor

DR. W. L. WILCOCK, at present reader in instrument technology at the Imperial College of Science and Technology, London, has been appointed to the recently instituted additional chair in the Department of Physics, with effect from October 1.

#### Liverpool

DR. A. YOUNG, at present reader in numerical analysis and director of the Computer Laboratory, has been appointed to the newly established chair of numerical analysis. Dr. N. M. Hancox, at present reader in histology, has been appointed to the newly established chair of histology. The following lecturers have also been appointed: Dr. J. V. Allaby, Dr. K. Bearpark, Mr. L. J.

Carroll, Dr. P. D. Forsyth and Mr. M. F. Thomas (physics); Dr. T. N. Calvey (pharmacology); Mr. T. L. J. Lawrence (animal husbandry).

#### Newcastle upon Tyne

PROF. W. F. K. WYNNE-JONES, head of the School of Chemistry, has been appointed pro-vice-chancellor to hold office until September 30, 1968. Prof. A. G. R. Lowden, Dean of medicine, has been appointed pro-vice-chancellor to hold office so long as he remains Dean of medicine. The following appointments have also been made: *Senior Lectureship*, Dr. D. C. Turk (microbiology). *Lectureships*, Dr. B. E. Johnson and Dr. J. S. Rose (mathematics); Dr. P. Grieseson (metallurgy).

#### Basic Plant Science at Michigan State University

THE new Plant Research Laboratory established at Michigan State University in conjunction with the Atomic Energy Commission has initiated its research programmes and is inviting applications for graduate study leading to a Ph.D. degree and for postdoctoral research associateships in various areas of basic plant science. Graduate degrees will be awarded through the appropriate academic department of the University. The Laboratory, under the direction of Prof. Anton Lang, is at present housed in adequate temporary quarters and will move into its own building in the spring or summer of 1966. By the autumn of 1965, research will be in progress in the following areas: function and mechanism of action of growth hormones, including hormonal control of enzyme activity; growth regulation through regulation of enzyme activity; cell wall metabolism; tissue culture; metabolic foundations of the control of plant growth by environmental factors; ageing of plant cells. Additional research areas will be available as the permanent research faculty is expanded. Further information concerning the programme of the Laboratory can be obtained from Dr. Lloyd G. Wilson, assistant to the director, MSU/AEC Plant Research Laboratory, Michigan State University, East Lansing, Michigan 48823. Applications for admission to graduate study should be addressed to the Director of Admissions, Michigan State University, East Lansing, Michigan.

#### The Night Sky in April

NEW MOON occurs on April 2d 00h U.T. and full Moon occurs on April 15d 23h. The following conjunctions with the Moon occur: April 5d 06h, Jupiter  $1^{\circ}$  N.; April 12d 12h, Mars  $2^{\circ}$  S.; April 27d 03h, Saturn  $4^{\circ}$  N. Mercury and Venus are not favourably placed for observation during the month. Mars sets at 5h 00m, 4h 05m, 3h 05m on April 1, 16 and 30, respectively, its stellar magnitude is  $-0.3$ ; its distance from the Earth on April 15 is 72 million miles and is in Leo. Jupiter sets at 22h 40m, 22h 00m, 21h 20m at the beginning, middle and end of the month, respectively; its stellar magnitude is  $-1.6$ ; its distance from the Earth on April 15 is 543 million miles and is in Taurus. Saturn rises at 5h 15m, 4h 10m, 3h 10m at the beginning, middle and end of the month, respectively; its stellar magnitude is  $+1.3$ ; its distance from the Earth on April 15 is 971 million miles and is in Aquarius. The following occultations of stars brighter than magnitude 6 occur, observation being made at Greenwich: April 5d 19h 48.8m, 43 Tau (*D*); April 7d 20h 22.6m, 5 Gem (*D*). *D* refers to disappearance.

#### Announcements

At a meeting of the Royal Microscopical Society, Dr. J. Baker announced that His Royal Highness the Duke of Edinburgh had accepted the office of president for the Royal Charter Centenary Year 1966. Mr. J. Bunyan is chairman of the Centenary Committee.

THE Institution of Chemical Engineers is to institute a medal in honour of George E. Davis, a pioneer in chemical

engineering and author of the first text-book on the subject. Dr. A. J. V. Underwood is to be the first to receive the award, which will be presented in London in the autumn.

PROF. N. N. GREENWOOD, head of the Department of Inorganic Chemistry in the University of Newcastle upon Tyne, has been appointed a member of the Panel on the Application of the Mössbauer Effect in Chemistry and Solid State Physics of the International Atomic Energy Agency (Vienna).

THE annual conference of the Ergonomics Research Society will be held at University College, Dublin, during April 5-9. Further information can be obtained from J. Spencer, 8-10 Berkeley Square, Bristol 8.

AN international symposium on "Scientific Aspects of Snow and Ice Avalanches" will be held in Davos during April 5-10. Further information can be obtained from the Swiss Federal Institute for Snow and Avalanche Research, 7260 Weissfluhjoch/Davos.

A CONFERENCE on "Industrial Diamonds in Metal-working", sponsored by the Haus der Technik, Essen, and De Beers Industrial Diamond Division, will be held in Essen on April 7. Further information can be obtained from the Haus der Technik, P.O. Box 668, Hollestr. 1a, Essen 43.

A MEETING of the Physical Biochemistry Group of the British Biophysical Society on "The Physical Chemistry of Separation Methods on Support Media" will be held in Cambridge on April 7. Further information can be obtained from Dr. P. Johnson, Colloid Science Laboratory, Free School Lane, Cambridge.

A CONFERENCE on "Elementary Particles", arranged by the Institute of Physics and the Physical Society, will be held in the University of Birmingham during April 5-7. Further information can be obtained from the Administration Assistant, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

A MEETING of the Basic Science Section of the British Ceramic Society on "Mechanical Properties of Non-metallic Crystals and Polycrystals" will be held in Birmingham during April 5-7. Further information can be obtained from Dr. J. P. Roberts, Houldsworth School of Applied Science, the University, Leeds 2.

A CONFERENCE on "Phenomena in the Neighborhood of Critical Points", sponsored by the U.S. National Bureau of Standards aided by a grant from the U.S. National Science Foundation, will be held at the Bureau during April 5-9. Further information can be obtained from Dr. M. S. Green, Statistical Physics Section, National Bureau of Standards, Washington, D.C.

A SYMPOSIUM on "Vibration in Civil Engineering", arranged by the British National Section of the International Association for Earthquake Engineering, will be held in the Imperial College of Science and Technology, London, during April 5-7. Further information can be obtained from the Secretary, British Section of the International Association of Earthquake Engineering, Institution of Civil Engineering, Great George Street, London, S.W.1.

A DEMONSTRATION meeting concerned with "Methods in Taxonomy" will be held by the Systematics Association at the British Museum (Natural History) on March 31. The meeting will consist of about fifty exhibits of methods and techniques used in taxonomy, arranged under the following headings: collecting; preparation and maintenance; examination and extraction of information; analysis and synthesis; dissemination of results. Further information can be obtained from W. G. Fry, British Museum (Natural History), Cromwell Road, London, S.W.7.

## ORGANIZATION OF RESEARCH AND TRAINING IN AFRICA

THE international conference on the "Organization of Research and Training in Africa in Relation to the Study, Conservation and Utilization of Natural Resources" was convened by the Director-General of the United Nations Educational, Scientific and Cultural Organization in accordance with a resolution adopted by the General Conference of that Organization, and was held at Lagos during July 28–August 6, 1964. The final report of the conference, now issued by Unesco\* in association with the United Nations Economic Commission for Africa, has chapters on national scientific policies from the point of view of research on natural resources; on the preparation and implementation of policies of research on natural resources; on scientific and technical personnel; on finance and research economics; on international co-operation in research on natural resources. It also includes the texts of speeches made at the opening and the closing of the conference. The recommendations adopted are given at the end of each chapter, and the outline of a plan for scientific research and training in Africa, which was agreed in a recommendation, is issued separately and discussed on p. 1141 of this issue of *Nature*.

The factual chapter on national scientific policies is probably the most realistic, giving concise summaries of the position in the 28 countries reporting. Appended to this chapter there is a brief statement of the imperatives of national science policy. These are listed as: realization by African Governments of the need to establish short- and long-term economic development programmes; recognition of the need to establish scientific research and industrial research programmes, both short-term and long-term; of their responsibility for organizing scientific research and encouraging research by creating a favourable atmosphere; recognition by scientists of their responsibilities towards their own countries; respect for

academic freedom and the right to free choice of methods and techniques; recognition of the need to establish a proper balance between fundamental and applied research; scientific collaboration at both regional and continental levels; establishment at the highest level of a body responsible for elaborating the national scientific policy and co-ordinating research activities; recognition of the need for study and research on natural resources and co-ordination of the activities of the bodies responsible; the necessity of training a sufficient number of research personnel as rapidly as possible and of the essential role of the universities in this respect; recognition of the need to include in all national budgets special provision for scientific and technical research.

The chapter on scientific and technical personnel estimates that the present total of research workers in Africa in natural resources may be some 2,280, but even a total of 5,000 would not give a ratio of research workers for the total population of more than 1 : 50,000. For the period 1965–80 a ratio of 200 scientific personnel and university science teachers per million inhabitants is suggested. In this total, experienced postgraduates, university graduates and technicians would be represented in ratios of 1 : 3 : 2.

The chapter on international co-operation recognizes that Africa is already receiving considerable assistance in this field from various Governments as well as from the United Nations, the Economic Commission for Africa and the specialized agencies, and it will be necessary to continue to strengthen and co-ordinate these efforts. It also admits that there are gaps in the present scientific structure, insufficient research workers and teachers, and inadequate financial resources, and that by 1980 some 50,000–70,000 research workers will be required from some source or other. Nevertheless, there is little appreciation of what has been done in the past in this field for Africa by individual Governments, or of the importance of ensuring conditions that will facilitate free international co-operation and interchange in any field of scientific endeavour.

## THE SCIENCE AND TECHNOLOGY BILL

THE debate in the House of Lords on February 4 on the Science and Technology Bill was of interest chiefly for some further information given by Lord Champion in moving the second reading. The Science Research Council would take over the present responsibilities of the Department of Scientific and Industrial Research for research grants to universities and postgraduate training awards, including grants for support of applied as well as pure science. Lord Champion said that the chairmanship of this Council, unlike that of the Agricultural and Medical Research Councils, would be held by a scientist as a full-time post.

Turning to the Natural Environment Research Council, Lord Champion stated that Sir Graham Sutton had accepted the invitation of the Secretary of State for Education and Science to be chairman of the new Research Council. However, Sir Graham would continue to devote most of his time to his responsibilities as director-general of the Meteorological Office, and a secretary of the new

Research Council would be appointed who would be a scientist holding appropriate qualifications. The Natural Environment Research Council would not be formally constituted until June, but the Science Research Council, for which the nucleus of a staff already exists in the Department of Scientific and Industrial Research, would be formed on April 1. Meanwhile, the activities of the component organizations under the Natural Environment Research Council would continue without interruptions, and on the dissolution of the Department of Scientific and Industrial Research the responsibility for making research grants to universities and postgraduate training awards in the field of interest to the Natural Environment Research Council would be taken over temporarily by the Science Research Council. Responsibility for the Geological Survey and Museum would be taken over temporarily by the Department of Education and Science.

Lord Champion went on to point out that responsibility for the Atomic Energy Authority had already, by Order

in Council, been taken over by the Minister of Technology. Under Clause 4 of the Bill the Authority would be able to extend its research functions outside the field of nuclear energy if the Minister of Technology so desired. This would enable the resources of skill, expertise and facilities in the Authority to be made available to support the Ministry in stimulating technological advance in industry if opportunity offered. Viscount Caldecote later suggested that it would be more appropriate to run down any strength not required in the Authority and transfer such highly qualified staff elsewhere in industry.

Lord Champion announced that an Order in Council was being laid that day bringing the National Research Development Corporation within the responsibility of the Minister of Technology, and it was hoped to introduce a Bill shortly which would increase the effectiveness of the Corporation. He said that a review was under way to establish the feasibility of orientating purchases and contracts in directions which would aid technological progress, including consideration of purchases made by the authorities directly and indirectly financed from public funds. The Minister of Technology was setting up

several technical appraisal teams of scientists, engineers and economists from within and outside the Government service to investigate the performance and products of sectors of industry, to identify any technological weaknesses, and to consider the ways in which these might be remedied. Other methods contemplated were the intensified placing of development contracts with industry, possibly under the supervision of the appropriate research station; steps to improve the supply and status of engineers; action to ensure that in the engineering field the British Standards Institution made the maximum contribution to the objectives of the Ministry. A suggestion from Lord Brown that the universities were themselves mainly responsible for the shortage of technologists and engineers and for failure to expand in this respect was stoutly refuted by Lord Chorley. Lord Snow, agreeing as to the importance of the status of engineers, added that he believed that the use of engineers could be radically improved by constructive action and by attempting to bring into other parts of industry not used to employing professional skill, the kinds of skill which were already used in the advanced industries.

## THE WELLCOME FOUNDATION, LTD.

IT was in 1880 that H. S. Wellcome, an American citizen by birth, came to England to partner S. M. Burroughs, and later to form Burroughs Wellcome and Company. On the death of Burroughs, Wellcome assumed sole control of the Company. His flair for commerce (he pioneered large-scale manufacture of tablets, with scientifically precise dosage, under the famous trade-mark 'Tabloid'); his drive, his profound belief in research, and his philanthropic outlook, these qualities combined to make possible the Wellcome Foundation and, later under the terms of his will, the Wellcome Trust, "... which applies the profits it receives to the advancement of medical and allied sciences and to the establishment or endowment of research museums and libraries throughout the world". The story of this Foundation, unique alike in character and structure, is well told and lavishly illustrated (much in colour) in a new publication\*. It is a document of considerable scientific interest and is well worth reading, especially by those concerned with prevention, control and cure of disease.

Although its headquarters are still in the familiar building in Euston Road, London, the ramifications of the Wellcome Foundation, through its subsidiaries and associated companies, Burroughs Wellcome International, Ltd., and Cooper, McDougall and Robertson, Ltd., are world wide. The chief operating centres are: Canada, Montreal; United States, New York and Chicago; South America, Rio de Janeiro, São Paulo and Buenos Aires; Europe, Paris, Brussels, Rome, Porirua; Africa, Nairobi, Salisbury and Johannesburg; Asia, Karachi and Bombay; Australia, Sydney; and New Zealand, Auckland. Prominence is given in this brochure to the Research Laboratories in the United Kingdom at Beckenham, Kent (Langley Court); to the Chemical Works at Dartford, Kent; and to the Veterinary Research Station at Frant, Kent. Many of the products of Cooper, McDougall and Robertson, Ltd., acquired by the Foundation in 1959, are manufactured in the Kelvindale factory, Glasgow, but the Cooper Technical Bureau is maintained at Berkhamsted, Hertfordshire, wherein is conducted research on insecticides, parasitic and bacterial diseases of animals, animal nutrition, chemical manufacture and pressure packing. Here, too, is the focus of collecting and recording scientific information. Some illustrated details are also

briefly given of the activities of the Company's overseas houses.

It is, however, when we come to examine some of the many outstanding achievements of the Foundation over the years that the impressive service it has rendered to mankind and animals becomes clearly manifest. As long ago as 1894 it was the first British company to produce diphtheria antitoxin. During 1904-14, Sir Henry Dale, then director of research, discovered and investigated histamine, acetylcholine and sympathomimetic amines, and showed how nerve impulses are transmitted. During 1921 the principles forming the basis of all methods of immunization were outlined. The period 1927-31 witnessed the discovery of diphtheria vaccines A.P.T. and T.A.F., also digoxin ('Lanoxin'); this was when the company introduced dog distemper prophylactics. In 1933 it was "... discovered that maternal antibodies in sheep are transferred from ewe to lamb in the first milk. From this have come the present-day methods of protecting lambs against many killing infections". In 1938 came the discovery of the antibacterial effects of sulphones, to-day the chief agents for treating leprosy. Between 1939 and 1949 came the discoveries of globin zinc insulin; the antibiotic polymyxin B ('Aerosporin', 'Thio-sporin'); the pharmacology of suxamethonium (succinylcholine), the short-acting muscle relaxant ('Anectine', 'Midarine'); and the issue of the first pure tubocurarine ('Tubarine'), the muscle relaxant for major surgical operations. In the decade 1952-62 were discovered the anti-cancer drug, mercaptopurine ('Puri-nethol'), the anti-malarial pyrimethamine ('Daraprim'), the anthelmintic bephenium ('Alcopar', 'Frantin'); and in 1962 azathioprine ('Imuran'), making possible transplantation of kidneys. In 1963 the company introduced methisazone ('Marboran'), the first antiviral chemotherapeutic compound, effective against smallpox.

This is a proud record. It is a remarkable tribute to that "blend of science, business and philanthropy" envisaged by the founder, Sir Henry Wellcome, LL.D., D.Sc., F.R.S., as he was when he died in 1936. In the Truman Wood Lecture to the Royal Society of Arts in 1963, Prof. E. B. Chain said: "Rarely can a contribution from a University laboratory have exceeded in theoretical or practical importance the discoveries which originated in the Wellcome Physiological Research Laboratories" (now part of the Wellcome Research Laboratories).

\* *The Wellcome Foundation, Ltd.* Pp. 52. (London: The Wellcome Foundation, Ltd., 1964.)

## TESTING PLASTIC FLOORING MATERIALS

THE testing and examination of plastic flooring materials such as asphalt, vinyl-asbestos, vinyl and linoleum, more particularly performance behaviour, continue to present certain practical difficulties. An objective attempt to clarify the position as it now is, and to prepare the way for further research on test procedures at present considered inconclusive, was recently made by M. J. Vix, chief research officer of the National Building Research Institute, South African Council for Scientific and Industrial Research, Pretoria\*.

The scope of this paper is comprehensive, embracing as it does the four materials quoted, each in respect of the examination of the following properties: flexibility; rittleness; curl; dimensional stability; resistance to abrasion, indentation, tear, scratching, detergents and cleaning solution, to fire and to cigarette burns; discoloration when exposed to solar radiation and to ultra-violet light radiation; acoustical properties; and slipperiness. The Tinius Olsen instrument (A.S.T.M. D747-50) was used to determine stiffness in flexure (lb./in.<sup>2</sup>), and despite their heterogeneous nature, a clear distinction between the different materials was obtained. Brittleness was assessed by the falling ball impact test (interim Federal specification L-T-751), only one sample of asphalt failing, from which is concluded that this standard test is only significant in cases of extreme brittleness. Tests for curl were made in accordance with the same specification; in some samples 'natural curl', regarded as an inherent defect, made testing of this property impossible. In the tests for dimensional stability (again in accordance with L-T-751) it was shown that vinyl-asbestos tiles showed greatest shrinkage; the largest average shrinkage was of the order of 0.1 per cent, in practice negligible. Vinyl flooring showed either shrinkage or expansion; it is suggested that a more suitable routine test should be used to detect excessive dimensional changes of more than 0.1 per cent.

Abrasion resistance was tested on a 'Taber' abrader (A.S.T.M. D1242-56) and also on a newly designed abrasion tester, of which details are given, developed by

the National Building Research Institute; the results indicate "... that the N.B.R.I. abrader shows values that are more comparable with actual wear than those obtained on the Taber abrader". Since the introduction of stiletto heel tips fitted with protruding nail-heads, resistance to indentation of these materials has become an increasingly important property; here again the test procedure accorded with the Federal specification L-T-751, but although vinyl appears to resist indentations better than the others, it is considered that conditions of temperature and time for this test method require further critical investigation. In the resistance to tear (A.S.T.M. D1004-49T), vinyl proved three times as good as other samples, but it is thought that the difference is not of much practical importance, 300-500 lb./in. compared with a minimum tear strength of 100 lb./in., desirable from the point of view of handling a flooring material. In the scratch test (L-T-751) asphalt tiles seem slightly less resistant than linoleum and vinyl-asbestos, while vinyl sheeting varied from very good to poor; some doubt on the efficiency of the scratch tester involved is raised.

Linoleum emerges worst as regards chemical attack. Resistance to fire, cigarette burns and extinguishing cigarettes, by the methods detailed, are somewhat inconclusive, but vinyl sheet showed the best rating on resistance to cigarette burns, linoleum the highest rating on "extinguishing cigarettes". The tests of discoloration when exposed to solar and ultra-violet radiations gave interesting but variable results, some of which are illustrated in two coloured plates; brief details are given. Methods of assessing acoustical properties and slipperiness are discussed.

The conclusions reached are that the following aspects of all this work need further investigation: influence of accelerated ageing on flexibility and abrasion resistance; influence of temperature on flexibility and indentation resistance; influence of chemical agents in relation to indentation testing; and the influence of polish and wax on floor slipperiness in relation to various soling materials. Altogether this paper is a valuable and most welcome contribution to problems of performance testing of these flooring materials.

\* *Rilem Bulletin*, Tome special. Symposium of Liège, 1964. Ref. RD 70. Pretoria: Council for Scientific and Industrial Research, 1964.)

## 'AEROLITE' AND 'ARALDITE' BONDING MEDIA

'AEROLITE' is a synthetic glue manufactured by Ciba (A.R.L.), Ltd., extensively used for bonding timber in building and other constructional work; examples are laminated wood members in building design, glued formwork for concrete emplacement, both recently noted *Nature*, 204, 129, 1139; 1964). The 'Araldite' range of epoxy resins, manufactured by the same firm, constitute the basis of formulations used *inter alia* for bonding metal to wood, as embedding media in biological research, for example, examination of animal and plant tissues in thin sections cut by microtome.

A specialized use of 'Aerolite' is in construction of timber building elements and particularly interior woodwork for churches and similar edifices. In this connection a recent publication, entitled *Church Furniture Bonded With Aerolite\**, is of some arboreal interest quite

apart from the efficacy of the gluing-medium concerned. It is pointed out that use of English oak in church structures and interior timber equipment is traditional; that the scarcity of really big oak trees in Britain to meet what were formerly considered essential dimensional requirements "in one piece" is now very real. "Oak members in the lantern of Ely Cathedral, built in the fourteenth century, are 64 ft. long and 3 ft. square, and it is said that the whole country was searched for trees big enough to supply these timbers. To-day, with many of the old forests gone, one would seek in vain for trees of this size and, even extending one's search much farther afield, one might well continue to be unsuccessful." To-day, large wooden structural members can be built up from relatively small pieces of oak or other timber to make any required unit size, with the aid of modern synthetic resin glue such as 'Aerolite'. The art of joinery as practised now by experts conceals glue-lines and,

\* Ciba (A.R.L.), Ltd., Technical Note No. 262, October 1964. Pp. 8. Oxford: Ciba (A.R.L.), Ltd., 1964.)

although the particular moulded member is composite, the resulting effect is that of solid timber, incidentally possessing extremely durable properties; since the structure of the unit is composite, inherent stresses natural to solid timber are reduced; there is little or no prospect of cracking or splitting. This publication describes and illustrates this type of work as carried out by Ebdons (Beddington), Ltd., of Croydon, who have had long experience of building church furniture and selecting the best possible timber for conditioning by kiln drying for this special purpose. Examples of this skilled workmanship in glued timber structures as shown include churches and chapels in Belham, Bromley, Walworth, Sutton and Cheam, Harting near Petersfield, and Eridge Castle, Sussex.

The use of 'Araldite' in bonding metal to woodwork is exemplified in the case of a processional cross (illustrated) which "... has the shaft reinforced with a steel rod bonded with Araldite epoxy resin. The same

adhesive is used for the bonding of metal fittings on communion rails, chairs, lecterns, etc.". In a later issue of Ciba Technical Notes†, an account is given of the use of "Araldite in Electron Microscopy". In this field it is used as an embedding medium of great stability. In the examination of animal and plant tissues with an ordinary laboratory microscope, paraffin wax is the standard embedding compound from which the requisite thin sections are cut by microtome; but with the electron microscope, exceptionally thin sections are required, and certain synthetic resins have been investigated. According to a report by Miss Audrey M. Glauert, Strangeways Research Laboratory, Cambridge, on which these technical notes are based, "... formulations based on Araldite epoxy resins have been found to be eminently successful, and such formulations have been adopted in research laboratories throughout the world".

## PHOTO-NEURO-ENDOCRINE EFFECTS IN CIRCADIAN SYSTEMS

IT is well established that the exact timing of 24-h rhythms is dependent on environmental influences, and that when all such influences are removed, although the rhythm may persist it is no longer synchronous with solar time but becomes free-running with a periodicity of anything between 20 and 28 h. The importance of the influence of daily changes of light and darkness on many daily and seasonal rhythms in both sickness and health has been recognized, if only dimly, since the times of Hippocrates. A great deal is now known about this influence of light on physiological processes and of the neuro-endocrine pathways involved. The *Proceedings* of a symposium on "Photo-Neuro-Endocrine Effects in Circadian Systems, with Particular Reference to the Eye"\* comprise a comprehensive survey, by the workers concerned, of the more recent additions to this knowledge. While there is some evidence that light waves, when they can penetrate sufficiently deeply, may act directly on hypothalamic structures in both avian and mammalian species, the more general influence of light on the sympathetic system is through a specific nervous pathway from the eye to the hypothalamus. Through the hypothalamic-hypophyseal connexions light can influence the endocrine discharges from the pituitary lobes. It is not surprising, then, to learn that the intensity and duration of light exposure can influence a great number of sympathetically and hormonally controlled physiological functions, particularly those of body temperature, reproduction and metabolism.

Halberg's term 'circadian', to describe the de-synchronized or free-running endogenous rhythmicity of only approximately 24 h, is now generally accepted, at least in North America, and is clearly defined in the course of Dr. Haguë's opening remarks. In some of the subsequent papers, however, no sharp distinction is made between the terms 'diurnal' (when used to describe a rhythm or activity over a period of 24 h) and 'circadian'. In a paper by Halberg and others, the term 'circadian' is extended to include "the special case of an exact 24-h period". This is consistent with Halberg's use, in another paper, of the word 'diurnal' in the more fundamental sense to describe an activity in relation to day-time, as opposed to 'nocturnal' and 'night-time'. Whether the term 'diurnal activity' used elsewhere in the volume describes an activity restricted to the day-time, or

during a 24-h period, is not at all clear. This is most confusing. In view of the stricture made on the use of the word 'circadian' by Williams in 1963<sup>1</sup>, it would be well if agreement could be reached on the use of these terms. We now have three distinct words and three distinct, or distinguishable, meanings which could be used as follows: (1) *diurnal*, that is, pertaining to the day-time, the complement to 'nocturnal'; (2) *nycthemeral* (or *nyc-themeral*, as used by French-speaking biologists), that is, relating to solar time, a period of 24 h, consisting of a night and a day (*Shorter Oxford English Dictionary*); (3) *circadian*, that is, the description of an approximately 24-h free-running endogenous rhythmicity. Perhaps the ambiguity of 'diurnal' is too deeply rooted for any plea for its eradication to be heard, but if the new term 'circadian' is to be wholly acceptable, its meaning must be made perfectly clear.

As is often the case with *Proceedings* of symposia by students of many disciplines and from many countries, this volume is not uniformly easy to assimilate, but it quickly arouses and sustains the interest of the reader. Strictly verbatim reporting of discussions can be irritating, especially when accompanying slides are not reproduced as figures. There is clear evidence, in at least one paper, of considerable alteration to the text subsequent to its original presentation. This would seem to destroy the whole premise for verbatim reporting elsewhere, and careful editing would not have obscured the valuable points which were sometimes raised in discussion. However, the symposium was well conceived, and was well balanced between the fundamental biological significance of the influence of light on physiological processes, and its considerable medical importance. While the subject-matter of some of the papers is not strictly within the terms of reference given in the title of the symposium, they afford a broader understanding of other inter-related factors which should not be ignored in a study of specific physiological processes. Papers on autonomic conditioning and the hypothalamic-hypophyseal neural influence in periodic diseases, for example, give depth to the more general consideration of the nature of biological rhythms, in both normal and abnormal conditions, while the two papers on control theory in relation to biological systems have even wider application and interest. This volume will be a valuable source of information for some long time to come.

HYBRIDIZATION OF NORMAL AND NEOPLASTIC CELLS *IN VITRO*

By LAWRENCE J. SCALETTA\* and BORIS EPHRUSSE†

Department of Biology, Western Reserve University, Cleveland, Ohio

THE occurrence of hybridization of somatic cells *in vitro* has been established in mixed cultures of several different pairs of permanent mouse cell lines<sup>1</sup>. The purpose of this communication is to describe the hybrids resulting from the mating of cells of a permanent line and freshly explanted diploid cells (the occurrence of these hybrids has been mentioned earlier<sup>1</sup>).

The permanent cell line used in our early experiments is Sanford's high cancer line NCTC 2472 of C3H origin<sup>2</sup>. The modal chromosome number of the stem line cells (1s) of 2472 is 49 (variation range: 46–51). Many 2s cells are always present in the population. All cells carry an extra long telocentric chromosome which is an excellent karyological marker; and some of them contain also a long bi-armed chromosome. In later experiments a clone (No. 6) of line NCTC 2472 was used, characterized by a mode of 50 chromosomes (variation range: 48–53). All cells of this clone contain the two aforementioned markers (Fig. 1). This clone contains very few 2s cells.

The normal cells are fibroblast-like cells derived from secondary cultures of skin of new-born CBA mice carrying the well-known T-6 translocation<sup>3</sup> among its forty telocentric chromosomes (Fig. 2). As can be seen in Fig. 3, the karyotype of the hybrid cells, immediately recognizable by the simultaneous presence of the marker chromosomes of the two parents, is essentially the sum of the two parental karyotypes. The hybrids between cells of clone No. 6 and those of T-6 have a modal chromosome number of 90 (variation: 87–92), as compared with the expected mode of 90 (variation: 88–93).

A low percentage of hybrid mitoses is detected within a few days after the initiation of mixed cultures. However, under the usual culture conditions, the hybrids rapidly disappear from the mixture. During the early stages of a mixed culture, the hybrids can, however, be isolated by cloning. This procedure has permitted the establishment of pure hybrid clones, which appear to be capable of indefinite propagation *in vitro*. Karyological analysis of these clones has shown that hybrids are formed by mating of diploid T-6 cells with both 1s and 2s cells of line NCTC 2472. Inoculation of 10<sup>6</sup> hybrid cells of these two types into C3H mice and F<sub>1</sub> mice from the cross C3H × CBA gave the results presented in Table 1.

Table 1

Cell line	C3H	F <sub>1</sub> (C3H × CBA)
NCTC 2472	19/19*	4/4
Hybrid 2472(2s)/T-6	14/18	6/6
Hybrid 2472 (1s)/T-6	7/11	—
T-6	—	0/5

\* Animals with tumours/animals inoculated.

It is clear that, in this case, the hybrids between cells of a 'permanent' neoplastic line and normal cells are both 'permanent' and neoplastic.

The decline of the percentage of hybrid cells observed at the usual culture temperature (36°–37°) does not occur if the mixed cultures are incubated at 28°–29°. At the lower temperature, the percentage of hybrid cells shows a rapid and continuous increase. Within a month after the beginning of an experiment, up to 99 per cent of the mitoses are of the hybrid type. The mechanism of this

Fig. 1. Metaphase of a cell of line NCTC 2472 (clone No. 6). Note the presence of an extra long telocentric and of a bi-armed chromosome (arrows)

Fig. 2. Metaphase of a diploid cell homozygous for the T-6 translocation (arrows)

Fig. 3. Metaphase of a hybrid formed in a mixed culture of NCTC 2472 (clone No. 6) and T-6. The marker chromosomes are indicated by arrows

effect of low temperature is being investigated on several somatic cell hybrids. If the low-temperature effect proves to be characteristic of other hybrids as well, it could be used as a tool for the selection of hybrids between cells carrying no special selective markers.

## A SELECTIVE SYSTEM FOR THE ISOLATION OF HYBRIDS BETWEEN L CELLS AND NORMAL CELLS

By RICHARD L. DAVIDSON\* and BORIS EPHRUSSI†

Department of Biology, Western Reserve University, Cleveland, Ohio

THE occurrence of mating between cultured cells of a permanent line and freshly explanted, normal cells has been recently demonstrated (previous communication). We have developed a system for the selection of such hybrids and for the determination of the rate of their formation. The purpose of this communication is to describe this system.

The permanent line used is A9, a sub-line of the L line, kindly supplied to us by Dr. J. W. Littlefield. A9 is resistant to 3  $\mu\text{g}/\text{ml}$ . of 8-azaguanine. (A similar line was used by Littlefield<sup>1</sup> to establish a selective system involving two biochemically marked L cell lines.) Cells of line A9 are heteroploid and contain 51–58 chromosomes (mode = 55), 18–20 of which are bi-armed. The normal cells are

Fig. 1. Metaphase of an A9 cell with 55 large and 2 very small chromosomes. Note the presence of 18 bi-armed chromosomes

Fig. 2. Metaphase of a diploid cell (40 chromosomes) homozygous for the T-6 translocation (arrows)

Fig. 3. Metaphase of a hybrid cell with 94 large and 1 very small chromosomes. Note the presence of 19 bi-armed chromosomes from A9 and of the two T-6 markers (arrows)

Fig. 4. Colonies of hybrid cells after two weeks in selective medium

fibroblast-like cells from secondary cultures of skin of new-born CBA mice carrying the T-6 translocation<sup>2</sup>. Hybrids between these two cell types are karyologically recognizable by the total number of chromosomes and the simultaneous presence of the parental markers (Figs. 1–3).

A9 and T-6 cells are mixed and either inoculated immediately into culture bottles containing a selective medium, or grown together for one or two days in Eagle's medium with 10 per cent calf serum, which is thereafter replaced by the selective medium. The latter is Eagle's medium with 10 per cent calf serum, supplemented with  $1 \times 10^{-4}$  M hypoxanthine,  $4 \times 10^{-7}$  M aminopterin, and  $1.6 \times 10^{-5}$  M thymidine, as in Littlefield's system<sup>1</sup>.

This selective medium prevents the growth of A9 cells<sup>1</sup>, and no revertants able to grow in this medium have been detected in our experiments. Aminopterin blocks the *de novo* synthesis of inosinic acid and thymidine. Therefore only those cells which can utilize exogenous hypoxanthine and thymidine grow in this medium. Since A9 lacks inosinic acid pyrophosphorylase, it cannot utilize exogenous hypoxanthine. The same medium does not interfere with the growth of T-6 cells, but since they are normal cells, they grow relatively slowly. On the basis of observations recorded in the preceding article,

\* Pre-doctoral fellow of the U.S. Public Health Service.

† On leave from the University of Paris.

we expected the hybrid cells, if formed, to grow rapidly and to produce multilayered colonies on a background of a *T*-6 monolayer. Such colonies are indeed observed after about two weeks in selective medium (Fig. 4). The evidence that all these colonies are produced by hybrid cells is as follows. A bottle containing a large number of colonies was examined cytologically, and almost all of the mitoses were found to be of the hybrid karyotype. The remainder were mitoses of *T*-6 cells. In another experiment, eight colonies were isolated and grown separately. Karyological examination showed that all of them contained hybrid cells.

When the selective medium is applied 1 day after initiation of the mixed culture, the number of colonies formed indicates that as many as one in 7,000 *T*-6 cells

had mated with A9 cells. It should be pointed out that, when the mixture is inoculated directly into the selective medium, more than half as many matings take place. Obviously, the selective medium does not immediately interfere with mating. This fact must be taken into account in calculations of mating rates.

Cultures of hybrid cells recovered from these experiments have been propagated by weekly transfer since October 1964, without decline in growth rate. Hence, the hybrids seem to have inherited from A9 this property of cells of a permanent line.

## INTERCHAIN DISULPHIDE BRIDGE IN BENCE-JONES PROTEINS AND IN $\gamma$ -GLOBULIN B CHAINS

By DR. C. MILSTEIN

Medical Research Council Laboratory of Molecular Biology, Hills Road, Cambridge

**N**ORMAL  $\gamma$ -globulins seem to consist of two A and two B chains. The B chains are linked to the A chains through an interchain disulphide bridge<sup>1</sup>. Isolated B chains are heterogeneous as shown by starch-gel electrophoresis<sup>2,3</sup>. Single molecular species of B chains have not been isolated from either normal or immunized individuals. The myeloma proteins, on the other hand, do not share this heterogeneity, possibly because they come from a single clone<sup>4</sup>. Bence-Jones urinary proteins are considered to be either very similar to or identical with the B (L) chains of the 7S myeloma proteins of the same individual<sup>5,6</sup>. The relationship between normal B chains and Bence-Jones proteins provides a way of investigating the heterogeneity of normal  $\gamma$ -globulin.

Bence-Jones proteins have been shown to occur as stable monomers, dissociable dimers and stable dimers<sup>7,8</sup>. Disulphide bridges are responsible for the stabilization of the dimers<sup>9</sup>. Investigations of one antigenic Bence-Jones protein of type I led to the suggestion that the cysteine residue involved in the interchain link of the B to the A chains was the same as the one involved in the stable dimerization, but that in dissociable dimers stabilization was prevented by the blocking of the —SH group with free cysteine. After performic acid oxidation the stabilized monomers yielded free cysteic acid<sup>9</sup>. The amount of cysteic acid liberated could be taken as a measure of the presence of dissociable dimers and stabilized monomers in a Bence-Jones protein preparation of type I. The presence of the same type of dimers and stabilized monomers has now been demonstrated in individual Bence-Jones proteins of type II.

Gel filtration of different Bence-Jones proteins on 'Sephadex G-100' in 1 M propionic acid gave rise to patterns in which a monomeric fraction was not always obvious. Three of these proteins (of which two are antigenic type II) gave the results shown in Fig. 1. The difference in the elution patterns of the three samples may possibly arise from differences in the stability of the dissociable aggregates. The fraction MA was not retarded at all by 'Sephadex G-100'; when re-run in the same system 90 per cent of the material appeared in the position of the fraction MB. Fraction MA is therefore thought to consist of aggregates of dimers. The occurrence of this type of aggregate may also explain the asymmetrical elution of XA. On the other hand, different proportions of dimers and monomers in equilibrium could be responsible for the difference in the positions of the more retarded peaks (BJC, MC, XB).

The amount of free cysteic acid obtained after performic acid oxidation of the different fractions is shown in Table 1. The yield in the more retarded peak (presumably stable monomer fractions) of each of the three preparations amounted to nearly 1 mole/mole of protein monomer, as should be expected if all the molecules contained an —SH group blocked with free cysteine. However, the amount of cysteic acid was in one case as low as 0.6 mole/mole of protein. The reason for this discrepancy is not clear; it might be related to the presence of an unidentified

Fig. 1. Fractionation of Bence-Jones proteins on 'Sephadex G-100'. The column was 3.5 cm diameter by 70 cm long and was eluted with 1 M propionic acid.

Table 1. FREE CYSTEIC ACID IN BENCE-JONES PROTEIN FRACTIONS OXIDIZED WITH PERFORMIC ACID

Fraction (Fig. 1)	Fraction eluting as cysteic acid in the amino-acid analyser (mole/mole)
Antigenic type I	
<i>BJB</i>	0.09
<i>BJC</i>	0.83
Antigenic type II	
<i>MA</i>	0.08
<i>MB</i>	0.05
<i>MC</i>	0.63
<i>XA</i>	0.24
<i>XB</i>	1.02

The pooled fractions (Fig. 1) were oxidized with performic acid (6-8 h at 0°). Samples were either analysed for cysteic acid in a Spinco amino-acid analyser or hydrolysed and analysed for basic amino-acids. Calculation of the molar ratios was based on the yield of basic amino-acids assuming an overall recovery of a total of 200 residues after 24 h hydrolysis with 5.7 N hydrochloric acid at 105°.

peak which appears in the chromatogram of the Spinco amino-acid analyser in a position between cysteic acid and carboxymethylcysteine. The substances which were less retarded in the 'Sephadex' column (dimers and higher polymers) released very little cysteic acid on performic acid oxidation, suggesting the presence of aggregated monomers.

**Interchain disulphide bridge in Bence-Jones proteins.** In a type I Bence-Jones protein the monomer and the dimer had been found to be stabilized by a disulphide bridge involving the C-terminal cysteine\*.

Stable monomer (type I):

— Lys.Ser.Phe.Asu.Arg.Gly.Glu.Cys  
|  
Cys

Stable dimer (type I):

— Lys.Ser.Phe.Asu.Arg.Gly.Glu.Cys  
|  
— Lys.Ser.Phe.Asu.Arg.Gly.Glu.Cys

A peptide with the composition (Lys,Ser,Phe,Asp,Arg,-Gly,Glu,CMCys) has now been isolated from normal carboxymethylated *B* chains from pooled human sera. The products of trypsin digestion of this peptide are consistent with the sequence already shown here. This sequence therefore appears to be common to many of the *B* chains of normal  $\gamma$ -globulin.

The type II Bence-Jones proteins (Fig. 1) were digested with pepsin, and the disulphide bridge peptides were located and isolated<sup>9,10</sup>. The peptic digests (enzyme substrate ratio 1/40; 16 h digestion time at 37° in 5 per cent formic acid) were subjected to ionophoresis at pH 6.5. The peptides carrying disulphide bridges were apparent after performic acid oxidation and ionophoresis at pH 6.5 in a second dimension. In both Bence-Jones protein fractions *MB* and *XA* (Fig. 1) three peptides were examined. They appeared to have similar electrophoretic properties and, according to sequence studies, were derived from the following disulphide bridge:

Stable dimers (type II):

— Lys.Thr.Val.Ala.Pro.Thr.Glu.Cys.Ser  
|  
— Lys.Thr.Val.Ala.Pro.Thr.Glu.Cys.Ser

The yield of 'monomer' obtained from one Bence-Jones protein (fraction *MC*, Fig. 1) was too low and no further work was done on it. Fraction *XB* (Fig. 1) was digested with pepsin and the cysteine peptides were located. The differences which could be detected between the 'monomer' and 'dimer' patterns were all related to the peptides described here, and were associated with the presence of a spot running as cysteic acid after performic acid oxidation. This suggests that, as in the type I protein, the monomer fraction of Bence-Jones *X* contains a disulphide bridge peptide involving a single cysteine residue; this replaces the disulphide bridge present in the dimer. A peptide (Thr<sub>2</sub>,Val,Ala,Pro,Glu,CMCys,Ser) has been isolated from normal carboxymethylated *B* chains indicating that

this sequence is also common to many of the normal *B* chains of human  $\gamma$ -globulin.

As in type I Bence-Jones proteins, the interchain disulphide bridge of type II appears to occur at the C-terminus of the protein. None of the peptic peptides examined contained any amino-acids following the serine residue. Tryptic digests of the proteins oxidized with performic acid gave a peptide with the composition (Thr<sub>2</sub>,Val,Ala,-Pro,Glu,CySO<sub>3</sub>H,Ser) (see following). As a confirmation, hydrazinolysis of the protein was performed and serine was obtained as the main C-terminal residue in both type II proteins in yields of about 0.9 mole/mole.

***B* chains and the interchain disulphide bridge of normal  $\gamma$ -globulin.** The following experiments were designed to examine the variation in the amino-acid sequence around the C-terminal cysteine which links the mixed population of *B* chains to the *A* chains to give the normal human  $\gamma$ -globulins.

*B* chains from normal pooled human sera were prepared in two ways. (1) Carboxymethylated chains were prepared as described in ref. 11 except that iodoacetate instead of iodoacetamide was used as the blocking agent and 'Sephadex G-100' instead of 'G-75' was used in the columns. (2) *B* chains oxidized with performic acid were prepared in a similar way, except that no blocking agent was used before separation of the chains in a 'Sephadex G-100', 1 M propionic acid column. Oxidation with performic acid was at 0° for 4-6 h. Trypsin digests were carried out with an enzyme substrate ratio of 1/50 in 1 per cent ammonium bicarbonate for 20-24 h at 37°. Fig. 2 shows an ionogram of the tryptic digests of several Bence-Jones proteins and of both performic acid oxidized and carboxymethylated *B* chains from normal  $\gamma$ -globulin. The band *T*<sub>1</sub> (Fig. 2) of type II proteins (*X* and *M*) contained only free cysteic acid, whereas those of performic acid oxidized and carboxymethylated *B* chains contained a peptide with the composition (Gly,Glu,CySO<sub>3</sub>H) or (Gly,Glu,CMCys), respectively. Type I protein (*BJ*) contained free cysteic acid and the peptide *T*<sub>1</sub> (Gly,Glu,CySO<sub>3</sub>H) in this region. In band *T*<sub>2</sub> (Fig. 2) type II proteins and normal *B* chains contained a peptide (*T*<sub>2</sub>) which was purified by electrophoresis at pH 3.5 and which had the composition (Thr<sub>2</sub>,Val,Ala,Pro,Glu,CySO<sub>3</sub>H or CMCys,Ser). These two peptides are considered to be the C-terminal peptides and also the interchain link in the Bence-Jones proteins under study.

The yield of these peptides was determined, so that an estimate of the minimum amount present in the whole

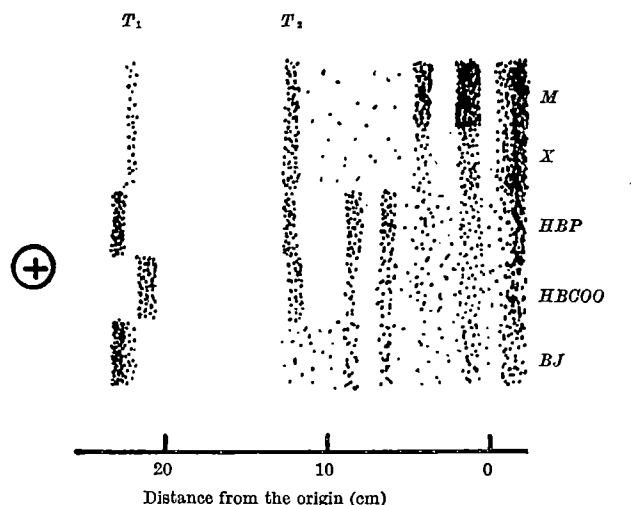

Fig. 2. Acidic components of the tryptic digests of Bence-Jones proteins and normal human  $\gamma$ -globulin *B* chains. The tryptic digest was applied to Whatman 3MM paper and subjected to ionophoresis at pH 6.5 (60 V/cm for 1 h). Bence-Jones proteins (*BJ*, *M*, *X*) were oxidized with performic acid before digestion. *HBP* and *HBCOO* were performic acid oxidized and carboxymethylated normal human *B* chains respectively.

Table 2. YIELD OF TRYPTIC PEPTIDES  $T_1$  AND  $T_2$  (FIG. 2)

Sample	Yield of peptide (mole/mole of starting protein)	
	$T_1$	$T_2$ *
type I (BJ)	—	—
type II (X)	0.7	0.5
normal B chains (oxidized with performic acid)	0.40–0.53†	0.16–0.24†
normal B chains (carboxymethylated)	0.28–0.30†	0.13

\* Peptide  $T_2$  was purified by electrophoresis at pH 3.5 (2 h at 60 V/cm, MM Whatman paper). To minimize losses in the transfer of the peptide, the sewing technique was used (ref. 14).

† Results of two independent determinations.

population of normal B chains could be made. The results are shown in Table 2. For comparison, the yields of the equivalent peptides from two Bence-Jones proteins (one of each type) are also shown. Since no correction for recoveries were made the results should be considered as minimum values. Considering this, the yields obtained with the performic-oxidized B chains are surprisingly high and suggest that all, or nearly all, the B chains in normal  $\gamma$ -globulins have either one or the other of the aforementioned C-terminal sequences. The proportion in which the peptides are found also suggests that their sequences are characteristic of the appropriate antigenic type, since it has been reported that in normal  $\gamma$ -globulin the type I and type II determinants occur in an approximate ratio of 2:1 (refs. 12 and 13).

The low yields of the carboxymethylated peptides compared to those obtained from the performic-oxidized B chains (Table 2) may have three explanations: (a) losses of carboxymethylated peptide occur during handling due to the lability of carboxymethyl-cysteine peptides; (b) all the B chains are linked to the A chains through these peptides, but during reduction and carboxymethylation disulphide interchange occurs, so lowering the yield of the carboxymethylated peptides; (c) not all the B chains are linked to the A chains through the C-terminal peptide. It is considered unlikely that the first mechanism could be responsible for the considerable discrepancies shown in Table 2. Disulphide interchange may have occurred, as preliminary experiments using radioactive iodoacetate led to the isolation of a third sequence, previously found associated with an intrachain disulphide bridge. If an interchain linkage other than that of the C-terminal

Table 3. SUGGESTED STRUCTURE AROUND THE INTERCHAIN DISULPHIDE BRIDGE IN HUMAN BENCE-JONES PROTEINS AND IN  $\gamma$ -GLOBULINS

$\gamma$ -globulin	—Lys.Thr.Val.Ala.Pro.Thr.Glu.Cys.Ser
	—Lys.Thr.Val.Ala.Pro.Thr.Glu.Cys.Ser
	A chains

peptide occurred naturally in normal B chains, one might find Bence-Jones proteins in which the disulphide bridge involved in the dimerization differs from the ones in two antigenic types described here.

Table 3 presents a summary of the suggested interchain disulphide links of Bence-Jones proteins and of the interchain link of most or all of the heterogeneous population of normal B chains. The results indicate that the two antigenic types of B chains are well-differentiated proteins. Each type should include a heterogeneity confined to a region or regions away from the C terminus.

I thank Prof. R. R. Porter, Dr. S. Cohen, and Dr. A. Feinstein for their gifts of classified Bence-Jones proteins.

## TEMPERATURE CONTROL OF THE RESPONSE OF TADPOLES TO TRIIODOTHYRONINE

By PROF. E. FRIEDEN, A. WAHLBORG and E. HOWARD

Department of Chemistry and the Institute of Molecular Biophysics, Florida State University, Tallahassee

THE influence of temperature on the metamorphosis of Amphibia was investigated as early as 1898 (ref. 1). In 1916 Adler<sup>2</sup>, observing histological changes in tadpole thyroids, concluded that environmental temperature determined the length of the larval period of *Rana temporaria*. After the relationship between the thyroid and anuran metamorphosis was discovered by Guderatsch<sup>3</sup>, it remained for Huxley in a Letter to the Editor of *Nature* in 1929 (ref. 4) to suggest the intimate relation between temperature and the response of the tadpole to moderate doses of thyroid powder. Although details of his experiments have never been published, Huxley reported that at temperatures below 5°, *R. temporaria* tadpoles treated with thyroid powder underwent partial metamorphosis and then ceased to change even when returned to room temperature. In urodeles, Hartwig<sup>5</sup> noted that in the 0°–5° temperature range the usual artificial effects of thyroxine could not be obtained in salamander larvae.

It is surprising that so few detailed investigations on the effect of temperature on the response of anura to thyroid hormones have been reported as revealed by several reviews<sup>6–10</sup>. Etkin<sup>8</sup> noted that tadpoles grow larger before undergoing metamorphosis at 16° than they do at 24°. Kollros<sup>11</sup> confirmed this and also mentioned experiments which indicated that the response to temperature is wholly or largely independent of the reactions of the thyroid gland, since hypophysectomized animals also showed a differential sensitivity to low concentration of thyroxine at different temperatures. In the most recent investigation available, Paik and Cohen<sup>12</sup> measured the increase in tadpole liver carbamyl phosphate synthetase during continuous immersion in  $2.6 \times 10^{-6}$  M (0.02  $\mu$ g/ml.) thyroxine at 15° and 25°. After a latent period, the specific activity of this enzyme at 15° increases about half as fast as it does at 25° and reaches a plateau at about half the maximum level attained at 25°. When these animals were brought to 25° the enzyme increase

Fig. 1. Effect of various temperatures on the response of tadpoles to a single large dose of  $T_3$ . Groups of eight *Rana grylio* tadpoles were injected with  $1.0 \times 10^{-7}$  moles/g tadpole at day zero. The decrease in tail-length was measured every day during periods of rapid change. Temperatures below 20° were maintained in special thermostatically controlled incubators housed in a cold room. The results in Fig. 1 were obtained from experiments performed simultaneously. Essentially no change was observed at 5° from the 7th to the 56th day. The initial fall in tail-length of the 5° curve appears to be an artifact since it was not observed in several subsequent experiments in which the per cent decrease in tail-length did not exceed 2 per cent in the first 10–20 days. The 5° control line refers to uninjected tadpoles.

Fig. 2. Effect of several temperatures on the response of tadpoles to a single moderate dose of triiodothyronine. Tadpoles were injected with  $3.0 \times 10^{-10}$  moles/g tadpole at day zero. The decrease in tail-length was measured every day during periods of rapid change.

was resumed without delay. In view of the lack of more extensive data, we decided to explore a wide range of temperatures, various periods of time and other conditions in order to determine the full significance of the temperature effect on induced metamorphosis.

In these experiments, we used the percentage decrease in tail-length to measure the metamorphic response of the tadpole to thyroid hormone. Groups of eight pre-metamorphic<sup>10</sup> *Rana grylio* tadpoles were treated with triiodothyronine ( $T_3$ ) and other thyromimetic compounds as described previously<sup>13–15</sup>. In every experiment a single injection of the hormone was administered on day zero. In early experiments, presented in Fig. 1, we attempted to force the tail response with a single massive dose of  $T_3$ ,  $1 \times 10^{-7}$  moles (65  $\mu$ g)/g tadpole. As the temperature was successively decreased from 25° to 7.5°, the rate of tail decrease was greatly reduced. At 5° no significant response to this large dose of  $T_3$  could be discerned even after 80–90 days. Thus, despite the use of at least 300–1,000 times an effective dose of  $T_3$ , the rate of response at 5° was less than 1 per cent of the rate of response at 25°. A similar experiment was initiated at much lower doses of  $T_3$ ,  $1 \times 10^{-10}$  (0.065  $\mu$ g) and  $3 \times 10^{-10}$  moles/g tadpole. As shown in Fig. 2, the response was proportionately reduced at 10° and completely absent at 5°. Similar data were obtained for thyroxine, 3'-isopropyl-3,5-diiodothyronine, and the propionic acid analogue of  $T_3$ . Estimation of the temperature coefficient,  $Q_{10}$ , over several temperature spans from the results in Fig. 2 gives a minimum value of 10. This large  $Q_{10}$  is not unprecedented for an overall biological process; but its size is unexpectedly great for a hormonal effect. The rate of tail response to  $T_3$  at 5° is less than one-hundredth of the rate at 25°. On this basis, assuming no other intervening factors, one might estimate that the larval life-span of a bullfrog might be extended in the cold from a minimum of one year to more than 100 years. However, in one experiment when tad-

poles approaching prometamorphosis<sup>10</sup> were treated with  $10^{-9}$  moles (0.65  $\mu$ g)  $T_3$ /g at 6°, slight but definite body shape changes and tail reduction were observed after several weeks. Thus, as expected, it appears that tadpoles at more advanced stages are more susceptible to  $T_3$  at low temperatures.

When tadpoles were injected on day zero with a low dose of  $T_3$ ,  $1 \times 10^{-10}$  moles (0.065  $\mu$ g)/g, held at 5° for extended periods, and then changed to 25°, a rapid  $T_3$  response was observed. This response curve, as shown in Fig. 3, parallels the curve which is obtained if animals are kept at 25° from the time of the initial injection of  $T_3$ , except that the two-day lag period is almost eliminated. Though not shown in Fig. 3, an identical result is obtained even if the removal to 25° is delayed to 80 days. No increase in the rate of metamorphosis of uninjected control animals has been observed when these animals were transferred to 25° after several months at 5°. This experiment eliminates the possibility that stimulation of the thyroid gland in the cold, as observed in the rat<sup>16</sup>, could account for these results.

In contrast to the foregoing experiments where the  $T_3$  effect proceeds when tadpoles are shifted from 5° to 25°, we have tried the converse experiment. Tadpoles were injected with  $T_3$ , maintained at 25° and then transferred to 5° at the end of the third, fourth and fifth days. As shown in Fig. 4, the tail response was arrested. Because of the relatively poor survival rate of these animals after the tenth day, the logical extension of these experiments—restoring the tadpoles to 25°—has succeeded for only a limited number of animals. With these animals, the tail decrease has always been renewed after restoration to 25°.

On the basis of these results, the remarkable temperature sensitivity and control of the response of tadpoles to exogenous thyroid hormone is now being investigated in our laboratory. The effect of temperature

Fig. 3. Restoration of the T<sub>3</sub> response at 25° after tadpoles were held at 5° for extended periods. A single injection of  $1.0 \times 10^{-10}$  moles/g tadpole was administered at day zero, and the decrease in tail-length was measured every day during periods of rapid change.

Fig. 4. Arrest of the T<sub>3</sub> response by lowering the temperature from 25° to 5°. Tadpoles were injected with  $1.0 \times 10^{-9}$  moles/g tadpole at day zero and held at 25°. Different groups were transferred to 5° after three, four, and five days, respectively. Arrows indicate the per cent decrease in tail-length of the group being transferred in addition to the day transferred. The small increase in response after the third day transfer at 10 per cent decrease in tail-length has been observed several times.

Other features of induced and spontaneous metamorphosis is now being investigated. The experiments described here raise two major questions which can be only briefly discussed now. The first question relates to what happens during the prolonged incubation at 5°. The ventral response of the tadpole when it is transferred to 5° could be due to: (a) an appreciable fraction of the T<sub>3</sub> surviving the prolonged incubation and becoming effective at 25°; or (b) T<sub>3</sub> initiating certain subtle preparatory changes at 5°, but a complete response to T<sub>3</sub> not ensuing until the temperature is increased. In order to attempt to answer this question, a preliminary estimate<sup>17</sup> of the biological half-life of the iodine of <sup>125</sup>I-T<sub>3</sub> in the tadpole has been made and found to be  $6 \pm 3$  h at 25° and about 12 days at 5°, when the original dose was  $1.00 \times 10^{-9}$  moles/g tadpole. Thus, after 60–80 days at 5°, less than 1 per cent of the original dose would be expected to remain. This level of hormone probably does not account for the rapid tail decrease observed when the tadpoles were transferred to 25°. Our tentative conclusion is that the hormone has already left its imprint on susceptible cells.

The possibility of subtle metabolic changes being produced by T<sub>3</sub> during the 5° incubation period is particularly intriguing because it would represent a dissociation or separation of metabolic changes during induced metamorphosis. The hormonal signal may have been received, but the low temperature will not permit the proper execution of the message. For example, the appropriate messenger RNA(s) could have been synthesized, but its impact on the protein synthesizing systems could be delayed or prevented at 5°. Thus, this may be a very valuable tool in the investigation of induction of differentiation by the thyroid hormone.

The second significant problem raised by this work is to explain how the metamorphic response can be so very dependent on temperature. It is known that many important biological reactions in homeotherms are extremely temperature sensitive. The thyroid hormone contributes to the ability of homeotherms to maintain a constant body temperature. At low temperatures, thyroid

hormone is secreted at a greater rate in the mammals; the rat, for example, produces three times as much thyroid hormone at 4° compared with 28° (ref. 16). But the temperature sensitivity of many key reactions of poikilotherms has not been widely studied. Where responses have been examined, much smaller temperature effects have been noted. The rate of liver carbamyl phosphate synthetase production decreases only about two-fold after T<sub>4</sub> stimulation over the 10° span of 25°–15° (ref. 12). A recent comparison<sup>18</sup> of the uptake of oxygen of tadpoles to 5° and 25° as described previously<sup>19</sup> showed that the respiration rate of young tadpoles at 5° is 14 per cent of the rate at 25° ( $11 \pm 2$  versus  $81 \pm 20$   $\mu$ l. oxygen/h/g tadpole). This results in a Q<sub>10</sub> for the respiration rate of about 2.7 compared with a Q<sub>10</sub> of about 10 for the tail response. While we are aware that the 'Q<sub>10</sub> Law' (a uniform response to temperature) does not necessarily hold for phenomena related to respiration of poikilotherms, it is clear that the relatively smaller difference in respiration at 5° and 25° cannot quantitatively account for the reduction in response to T<sub>3</sub> at 5°.

We regard the blocking of the metamorphic response by low temperatures as a basic clue to the kind(s) of reaction which might be affected by the thyroid hormones. For example, we might expect characteristic phase changes in certain lipid structures to occur between 0° and 10°. Numerous enzymes undergo marked alterations in temperature coefficients in this range which are not related to phase changes. It is possible that the particular enzymes directly involved in tail resorption could show an unusual temperature sensitivity. It is also known that vital changes in the structure of water (icebergs) occur around 5°. Perhaps certain acute alterations in water–biopolymer, RNA–protein, RNA–DNA or DNA–DNA interactions can also occur in the 5° region. On the other hand, the binding of T<sub>3</sub> by protein would have to be unexpectedly temperature-sensitive to account for the difference in response at 5° and 25°. It is also possible that the large temperature coefficient represents the sum of numerous co-operative effects analogous to protein denaturation. It is hoped that one or more of these

approaches will lead to experiments which will help elucidate the nature of the temperature effect on the response of the tadpole to  $T_3$  or  $T_4$  and perhaps the basic mechanism of action of the thyroid hormone.

## UPTAKE OF INSULIN LABELLED WITH IODINE-131 BY ELASTIC TISSUE IN VITRO

By DR. MARIA G. BUSE, DR. DOUGLAS J. JONES and  
PROF. W. CURTIS WORTHINGTON, jun.

Departments of Medicine and Anatomy, Medical College of South Carolina, Charleston

RECENT autoradiographic investigations of the distribution of exogenous radioiodinated insulin in the rat have demonstrated an affinity of this hormone, or its breakdown products, for elastic fibres and membranes<sup>1</sup>. However, information concerning quantitative differences in insulin 'binding' between elastic and other tissues is lacking. One purpose of this article is to report quantitative differences in the *in vitro* uptake of insulin-<sup>131</sup>I by slices of the bovine ligamentum nuchae (consisting predominantly of elastic fibres) and the uptake by slices of tendon and striated muscle.

Pieces of ligamentum nuchae, tendon and superficial cervical muscle from freshly killed cattle were immersed in cold mammalian Ringer's solution and used within 3 h. Slices of approximately 1 mm thickness and 1.0 × 0.6 cm were cut perpendicular to the length of the fibres, placed in individual tared vaccine bottles containing 2 ml. of incubation medium with the radiolabelled substrate and reweighed (± 0.1 mg). The tissues were incubated with shaking in an atmosphere of oxygen and carbon dioxide (95:5), pH 7.4, for 10, 30, or 60 min at either 37.5° or 4° C.

After incubation the slices were rinsed for 30 sec in iced buffer and blotted, and the radioactivity was measured immediately in a γ-scintillation well-counter. They were then washed for 60 min in two 20-ml. changes of buffer at 4° C, recounted in the well-counter, dried in an oven at 110° C for 2 h and weighed. The degradation of the labelled insulin in the medium during incubation was measured as the fraction of the radioactive material which was soluble in trichloroacetic acid (TCA)<sup>2</sup>.

Gey and Gey's balanced salt solution<sup>3</sup>, supplemented with glucose (1 mg/ml.) and crystallized bovine serum albumin (Armour Pharmaceutical 6, Kanehake, Illinois) (5 mg/ml.), was used for the incubation medium. The albumin was added to minimize the adsorption of insulin to glass<sup>3</sup>.

All labelled materials were stored at 4° C. Crystalline beef insulin labelled with iodine-131 (Abbott Laboratories, Oak Ridge, Tenn.) was used on the day following its preparation by the manufacturer. The products of spontaneous degradation or radiation damage represented 1.2–2.6 per cent of the radioactivity when evaluated by hydrodynamic-flow paper chromatography<sup>4</sup> and 0.1–2.6 per cent of the radioactive material was soluble in TCA.

In two experiments insulin-<sup>131</sup>I was inactivated by reduced glutathione (GSH) according to Du Vigneaud *et al.*<sup>5</sup>. Following reduction, 21.5 per cent of the radio-

active material was soluble in TCA and 78 per cent migrated with the degradation products of insulin-<sup>131</sup>I during hydrodynamic-flow paper chromatography.

The concentration of radioactivity in the incubation medium was approximately 0.25 μc./ml. medium representing 30–40 mug insulin-<sup>131</sup>I/ml. or 25 μg radioiodinated- (<sup>131</sup>I labelled) human serum albumin (RISA) (Abbott Laboratories, Oak Ridge, Tenn.)/ml. With the equipment used, 0.25 μc. registered approximately 120,000 c.p.m. over a background of 20 c.p.m. Tissue radioactivity was expressed as the *T/M* ratio, where *T* represents counts per min (c.p.m.)/g tissue (wet weight) and *M* is c.p.m./ml. incubation medium. In Figs. 2b and 4b, *T* represents c.p.m./g tissue dry weight.

There was no significant difference in the concentration of radioactivity found in the different tissues following 10-min incubation at 37.5° C in the presence of insulin-<sup>131</sup>I. However, after 30- or 60-min incubation the concentration of radioactivity in elastic ligament was approximately twice that in tendon (*P* < 0.01) and approximately three times greater than in muscle (*P* < 0.01). Elastic ligament

Fig. 1. Radioactive material in slices of elastic ligament, tendon and muscle following incubation at 37° C in a medium containing insulin-<sup>131</sup>I. a, Slices counted immediately after incubation. b, Slices recounted after a 60-min wash in buffer without radioactive substrate at 4° C. Each point is the mean of six tissue slices ± S.E.M. ●—●, Elastic ligament; ▲—▲, tendon; ×—×, muscle.

concentrated the radioactivity against a gradient, since the  $T/M$  ratio exceeded unity after 30- and 60-min incubation (Fig. 1a).

Washing for 1 h at 4° C removed more radioactivity from tendon than from muscle ( $P < 0.01$ ), but proportionally less from elastic ligament than from tendon ( $P < 0.01$ ) or muscle ( $P < 0.05$ ). As a result, the difference between elastic ligament, on one hand, and tendon and muscle on the other, becomes more pronounced after washing. Elastic ligament which was exposed to insulin- $^{125}$ I for only 10 min contained 60 per cent more radioactivity than tendon ( $P < 0.01$ ) and 130 per cent more than muscle ( $P < 0.01$ ). After 30- or 60-min incubation elastic ligament contained approximately four times more radioactivity than either tendon or muscle ( $P < 0.01$ ) (Fig. 1b).

A comparison of the degradation of insulin- $^{125}$ I in the medium by the three types of tissue during incubation at 37.0° C is given in Table 1. Each of the tissues exhibited some 'insulinase' activity, since, during 60-min incubation, the TCA precipitable fraction of the radioactivity decreased in all media. Muscle degraded more insulin- $^{125}$ I than either tendon or elastic ligament ( $P < 0.01$ ), whereas the activities of the latter two were equal and relatively weak. Therefore, the affinity of elastic tissue for insulin- $^{125}$ I is not related to its 'insulinase' activity.

Table 1. DEGRADATION OF INSULIN- $^{125}$ I IN THE MEDIUM DURING INCUBATION WITH SLICES OF ELASTIC LIGAMENT, TENDON OR MUSCLE AT 37.5° C

Incubation (min)	Per cent TCA-precipitable radioactivity in medium*		
	Elastic ligament	Tendon	Muscle
10	98.9 ± 0.58	98.2 ± 0.75	97.2 ± 1.01
30	96.7 ± 0.37	97.1 ± 0.70	92.4 ± 0.88
60	91.0 ± 2.04	90.0 ± 1.95	81.4 ± 2.00

\*  $\frac{\text{TCA precipitable c.p.m./ml. medium}}{\text{Total c.p.m./ml. medium}} \times 100$

Each value represents the mean of 6 tissue slices studied in 3 separate experiments  $\pm$  S.E.M. Before incubation 97.5–99.9 per cent of the radioactivity in the medium was precipitable with TCA.

The greater density of elastic ligament could increase the number of available 'binding sites' per g tissue. The total tissue water of the slices represented in Fig. 1 was  $5.6 \pm 0.51$  per cent of wet weight in elastic ligament,  $0.7 \pm 1.11$  per cent in tendon, and  $81.5 \pm 0.49$  per cent in striated muscle. Thus, although the dry weight/wet weight ratio is greater in elastic ligament than in tendon or muscle, the difference is not large enough to account for the preferential concentration of insulin- $^{125}$ I by elastic ligament. Indeed, when the results illustrated in Fig. 1b are recalculated on the basis of the dry weight of the tissues, the concentration of radioactive material in elastic ligament was still significantly greater ( $P < 0.01$ ) than that in tendon or muscle following 10-, 30- or 60-min incubation with insulin- $^{125}$ I. This fact is further illustrated in Fig. 2b.

Fig. 2. Radioactive material in slices of elastic ligament, tendon and muscle after incubation at 4° C in a medium containing insulin- $^{125}$ I, followed by washing for 60 min at 4° C in buffer without radiolabelled substrate. The radioactivity present in the tissues after washing is related to the wet weight of the slices in a and to the dry weight in b. Each point is the mean of two tissue slices  $\pm$  S.E.M. Symbols as in Fig. 1

Fig. 2 shows the concentration of radioactivity in each type of tissue after incubation with insulin- $^{125}$ I at 4° C, followed by washing for 1 h at 4° C. More radioactive material was 'bound' to slices of elastic ligament than to tendon or muscle ( $P < 0.02$ ), although the total uptake by each tissue was less than when incubated at 37° C. The results are essentially identical, whether the values are expressed on the basis of the wet weight or the dry weight of the tissues (compare Figs. 2a and 2b). The radioactive material in the medium was 98–99 per cent precipitable with TCA following incubation, indicating that insulin- $^{125}$ I was not degraded by the tissue slices at 4° C and that the material which was preferentially concentrated by elastic tissue was not a product of enzymatic degradation. The affinity of elastic tissues for insulin at 4° C suggests that the reaction can occur under conditions of minimum metabolic activity.

The rate of diffusion of the labelled protein through tissue slices may be a factor which determines its concentration in the slice after incubation. To test this hypothesis, tissue slices were incubated at 37.5° C, with albumin- $^{125}$ I (RISA) (Fig. 3). All tissues contained significantly less radioactive material when RISA was substituted for insulin- $^{125}$ I in the medium ( $P < 0.01$ ) (compare Fig. 3a with Fig. 1a). The greatest concentration of radioactivity in tissue after incubation with RISA (Fig. 3a) was approximately 40 per cent of the concentration in the medium. Tendon contained more radioactivity than elastic ligament although the differences between tissues were not significant. RISA did not penetrate faster into elastic tissue slices than into slices of tendon or muscle. Washing for 1 h removed most of the radioactivity from all tissues (Fig. 3b). The concentration of radioactivity in the tissues after washing was less than 10 per cent of that in the medium, and there was no significant difference between the three types of tissue.

Fig. 3. Radioactive material in slices of elastic ligament, tendon and muscle following incubation at 37° C in a medium containing radioiodinated human serum albumin (RISA). a, Slices counted immediately after incubation. b, Slices recounted after a 60-min wash in buffer without radioactive substrate at 4° C. Each point is the mean of three tissue slices  $\pm$  S.E.M. Symbols as in Fig. 1

Exposure to GSH in a nitrogen atmosphere causes the reduction of the S—S linkages of insulin and inactivation of the hormone<sup>6</sup>. Tissue slices were incubated at 37.5° C with GSH-reduced insulin- $^{125}$ I, then washed for 1 h at 4° C (Fig. 4). The concentration of radioactivity by elastic ligament incubated with 'intact' insulin- $^{125}$ I in other experiments is shown for comparison. Elastic tissue 'bound' significantly less radiolabelled material during 30–60-min incubation with GSH-reduced insulin- $^{125}$ I than with unaltered insulin- $^{125}$ I ( $P < 0.01$ ) (Fig. 4a), while tendon and muscle 'bound' insulin- $^{125}$ I and GSH-reduced insulin- $^{125}$ I equally (compare Fig. 1b with Fig. 4a). Thus, reducing the S—S linkages of insulin- $^{125}$ I decreased the affinity of the elastic tissue for the labelled material. However, after 30 or 60 min incubation with GSH-reduced insulin- $^{125}$ I the concentration of 'bound' labelled material was still greater in elastic ligament than in tendon or muscle ( $P < 0.02$ ), when calculated on the basis of the wet weight of the tissues (Fig. 4a). This

Fig. 4. Radioactive material in slices of elastic ligament, tendon and muscle after incubation at 37° C in a medium containing insulin-<sup>125</sup>I treated with reduced glutathione, and washing for 60 min in cold buffer (4° C) without radioactive substrate. The radioactivity contained in the tissues after washing is related to the wet weight of the slices in *a* and to the dry weight in *b*. Each point is the mean of three tissue slices  $\pm$  S.E.M. ■, Elastic ligament incubated with insulin-<sup>125</sup>I. Other symbols as in Fig. 1 and incubated with GSH-reduced insulin-<sup>125</sup>I.

could indicate that the affinity of elastic tissue for insulin is only partially dependent on intact S—S linkages in the insulin molecule, or that the reduction of insulin-<sup>125</sup>I by GSH was incomplete. All tissues 'bound' some GSH-reduced insulin-<sup>125</sup>I, since the radioactivity remaining in the tissue slices after washing was greater following incubation with GSH-reduced insulin-<sup>125</sup>I than with RISA. The protein content of the tissues may be important. When the concentration of radioactive material in the tissues is calculated on the basis of their dry weight (Fig. 4*b*) there is no difference in the amount of radioactive material bound by elastic ligament or muscle during incubation with GSH-reduced insulin-<sup>125</sup>I.

Although the specificity of insulin binding *in vitro* has recently been questioned<sup>6</sup>, binding of insulin to the target tissue is thought to be a prerequisite for the biological action of insulin *in vivo* and *in vitro*<sup>7-9</sup>. It does

not necessarily follow, however, that the mere fact of binding indicates that biological activity is taking place.

There is at present no evidence that insulin in any way affects elastic tissue or that the elastic tissue affects insulin or that the marked ability of elastic tissue to 'bind' insulin influences the overall metabolism of this hormone. Its mere presence, however, in such relatively large amounts presents a situation which cannot be ignored. Camerini-Davalos and associates have demonstrated by electron microscopy<sup>10</sup> degenerative changes in elastic tissue of prediabetics. There might be some connexion between the selective affinity of insulin for elastic tissue and these degenerative changes. One could speculate that insulin, or the lack of it, may have some effect on the metabolism of elastic tissue or could in some way affect the physico-chemical properties of elastic fibres or membranes. One might also speculate that insulin which binds to elastic tissue may become available to the body economy in certain circumstances. Finally, the unusual affinity of insulin for elastic tissue might give us an insight into the nature of binding sites of insulin in tissues in general.

## ACTIVITY OF A TUMOUR POLYSACCHARIDE SUBSTANCE ON MICE TRANSPLANTED WITH SARCOMA 180

By PROF. JACK G. MAKARI\*

South Plainfield, New Jersey

IT was predicted by Burnet and Fenner<sup>1</sup>, and consequently demonstrated experimentally by Medawar *et al.*<sup>2,3</sup>, that a state of immunological unresponsiveness or tolerance results from the neonatal presentation of an antigen to an animal. This work was extended by a number of investigators<sup>4-6</sup> who showed that animals can be rendered immunologically tolerant to protein antigens by means of neonatal presentation of the antigen.

Siskind, Patterson and Thomas<sup>7</sup> have shown that both unresponsiveness and immunity can be induced in newborn and adult mice with pneumococcal polysaccharide, high dosage resulting in unresponsiveness while small dosage results in immunity. The basic concept underlying such investigations is that described by Felton and Ottinger<sup>8</sup> and later by Felton<sup>9</sup> and Felton *et al.*<sup>10</sup> and referred to as "Felton's immunological paralysis". Felton *et al.* reported that adult mice which received a relatively large dose of pneumococcal capsular polysaccharide succumbed on subsequent challenge with virulent pneumococci of the same type. In contrast, mice which received a relatively small dose of the same type of polysaccharide survived the challenge.

\* Present address: 17 Steven Terrace, South Plainfield, New Jersey.

Koprowski<sup>11</sup> demonstrated the induction of tolerance to tumour tissues in a host animal following intra-foetal injection of tumour cells. This finding brought to the concept of immunoparalysis nearer to the cancer field. However, in order to understand better the relationship between immunoparalysis and cancer it is necessary to make further simplifications (in terms of chemically identifiable substances prepared from cancer tissue) when attempting to determine the particular antigens responsible for immunity and susceptibility to cancer.

Earlier<sup>12-14</sup> evidence was presented by me for the polysaccharide nature of cancer antigens—referred to as 'tumour polysaccharide substance' (TPS). Prof. J. Smith *et al.*<sup>15</sup> have now demonstrated that TPS has characteristics similar to a glycoprotein. In studies with the Schultz-Dale reaction, I was able to show that TPS can induce immunity in small dosage and immunoparalysis in larger dosage<sup>16</sup>. In other investigations with cutaneous hypersensitivity in man<sup>16</sup>, I was able to show that TPS forms complexes with other macromolecules such as DNA, which are themselves antigenic. Plesci Braun and Paleyuk<sup>17</sup> have recently identified such complex of a polysaccharide antigen associated with

DNA from Ehrlich-Lettre mouse ascites tumour cells. In an immunological unitarian concept of cancer which I described earlier<sup>10,18,19</sup>, TPS was assigned the key role, the 'common denominator', in carcinogenesis. It was postulated that this abnormal polysaccharide is formed in tissues in response to chronic and prolonged irritation by the many carcinogenic agents—chemical, viral and physical—by the alteration of the normal polysaccharide substance which is believed to surround all cells (such as the erythrocyte receptors<sup>20</sup> and the tissue transplantation antigens<sup>21,22</sup>) and which also reside in abundance in the connective tissue of the host. More recently, Defendi and Gasic<sup>23</sup> have demonstrated a thick coat of acid mucopolysaccharides in hamster embryo cells transformed *in vitro* by polyoma virus.

The formation of TPS, according to this concept, triggers off a series of events in the host, starting with immunity to TPS (analogous to the homotransplantation reaction), immunoparalysis to TPS, followed by the development of an embryonic type cell (the result of interaction by TPS of cell-stromal interaction), and leading to the development of an immunologically competent neoplastic cell (the result of alteration of the nucleic acids of the cell by TPS).

These investigations were carried out in an attempt: (1) to test further the validity of the immunological unitarian concept of cancer which I postulated earlier; (2) to understand better the chemical basis for immunity and unresponsiveness in preconditioned mice transplanted with sarcoma 180; and (3) to localize tumours by the use of tritiated TPS (<sup>3</sup>H-TPS). This latter approach was based on two earlier findings: first, that tumour cells are immunologically competent, producing or concentrating both antibodies as well as antigens<sup>24-26</sup>; secondly, that tritiation of TPS does not alter its antigenicity. In other experiments (to be published elsewhere) I was able to induce *in vitro* anaphylaxis in properly sensitized uterine segments with the labelled substance (<sup>3</sup>H-TPS) at the same level of sensitivity (that is, at the 5 µg level) as the unlabelled material. By the use of <sup>3</sup>H-TPS it was hoped to reach selectively the neoplastic cells with the β-emitting isotope without injuring the neighbouring normal cells—a situation which may result in the cure of the tumour-bearing host.

The following macromolecules were used in these experiments:

(1) TPS-sarcoma 180 (TPS-*m*). This tumour polysaccharide substance was prepared from the mitochondrial fraction of sarcoma 180 tumour tissue of mice (that is, at a fraction which sediments between 3,000 and 1,000 r.p.m.). This fraction was then subjected to various chemical procedures as described earlier<sup>12</sup>.

(2) NPS-*m*. This normal polysaccharide substance was prepared from normal mouse lung of the same type AKR/J mice used in the experiments. The procedure of isolation and purification was the same as that used for TPS-*m*.

(3) <sup>3</sup>H-TPS-sarcoma 180 (<sup>3</sup>H-TPS-*m*). This is the tumour polysaccharide substance obtained from sarcoma 180 of mice which has been tritiated by the Wilzbach procedure<sup>27</sup> by the New England Nuclear Corporation. The specific activity of this batch was 0.073 mc. per mg. This material was dialysed against phosphate buffer pH 6.8 for 21 days at 5° C. Each time 500 ml. of buffer is used and changed every 4 days. Only 1.47 per cent of the initial activity was retained.

(4) DNA-sarcoma 180 (DNA-*m*). This deoxyribonucleic acid was prepared from the nuclear fraction of sarcoma 180 tumour tissue (that is, the fraction which sediments at 3,000 r.p.m.). The sediment was treated with freon (2 volumes of freon, 1 volume of sediment, volume of 0.15 M sodium chloride) for 5 min in a Virtis homogenizer at 15,000 r.p.m. with the homogenizing cup cooled in ice. It was then centrifuged at 3,000 r.p.m. for 5 min in a Lourde refrigerated centrifuge. The
